In 1997 the manufacturers of fen-phen, the abbreviation for a combination of the two weight-loss drugs fenfluramine and phentermine, withdrew the supplements from the market. Preliminary research showed that they caused heart valve problems in some patients. Physicians were concerned that this drug combination could affect the heart valves because the drugs alter the metabolism of serotonin in the body. Serotonin is a natural substance found in the brain and intestines that can affect blood vessels. Until the issue could be studied more, physicians recommended that patients taper off the drugs, finally stopping them altogether. Eventually, the company reached a $3.75 billion settlement of most lawsuits by former users of the diet drugs.

Other valvular heart disease

The mitral and aortic valves may also be affected by deposits of **calcium** in the heart that occurs with **aging**, which can lead to thickening and leakage of

heart valves. Heart attacks also can damage the mitral valve structures. Additionally, certain connective tissue disorders can adversely affect the heart valves, for example, Marfan's syndrome and myxomatous degeneration.

Diagnosis

Specific types of valvular heart disease are diagnosed using **electrocardiography** (EKG or ECG), **echocardiography**, certain x-ray studies, **magnetic resonance imaging** (MRI), **stress** testing, and/or **cardiac catheterization**. An EKG provides a record of electrical changes in the heart muscle during the heartbeat. Echocardiography uses sound waves to make images of the heart. These images can show if there are any abnormalities of the heart valves. Stress testing, which is often called treadmill tests, measures heart rate, blood pressure, ECG changes, and breathing rates during **exercise**. Cardiac catheterization, also called an angiogram, is a procedure in which a small tube (called a catheter) is inserted into an artery and passed into the heart. It is used to measure pressure in the heart and the amount of blood pumped by the heart.

Rheumatic fever

Rheumatic fever may be suspected when a recent throat infection has occurred and other major or minor symptoms appear, such as joint ache, abnormal EKG, or a blood test indicating heart inflammation. **Heart murmurs** may be detected from routine examination.

Infective endocarditis

A diagnosis of infective endocarditis can be obtained through patient history, EKG, **ultrasound**, or cardiac catheterization. Patients who have rapidly developed the disease may report fever, fatigue, night sweats, chills, and joint inflammation. Those who have developed the disease more slowly will show signs of rapid heart rate, an enlarged spleen, various skin colors or spots, and heart murmur. The physician may order blood tests to determine what is causing the infection.

Appetite suppressants

People with a history of using appetite suppressants may be sent for EKGs or further testing if any of the symptoms of valvular heart disease, such as swelling, considerable fatigue, or shortness of breath occur.

Treatment

The treatment of specific valvular heart diseases will vary, depending on the valve involved and the extent of damage or malfunction. Some patients do not require treatment and many are treated with medication. Sometimes, patients need surgery. If multivalvular disease is suspected or involved, different valves may be evaluated during surgery on one of the affected valves. Valve surgery may repair a damaged valve or replace one that is unable to be repaired. Replacement valves are made from artificial materials (called prosthetic valves) or from natural tissues of animals (called bioprosthetic valves). A balloon dilation technique is used to widen a stenotic valve with the use of a small balloon that is inserted into the narrowed valve with a catheter. Women with heart valve disease who want to become pregnant should receive a thorough check-up and see a cardiologist regularly throughout their **pregnancy**.

Rheumatic fever

Patients with rheumatic fever are treated with **antibiotics** to eliminate streptococcal organisms that may still remain in the heart. Patients may receive antibiotics to prevent further infection, and inflammation may be treated with **aspirin** or cortisone-like drugs.

Infective endocarditis

Physicians will use the appropriate antibiotic or some combination of antibiotics to treat infective endocarditis, depending on the type of bacterium that caused the disease. Severe cases of this disease may be corrected by valve replacement surgery.

Appetite suppressants

The role of appetite suppressants (fen-phen) in valvular heart disease has been studied. Many of the people who suffered complications of the diet drugs experienced regurgitation.

Prognosis

The prognosis for patients with valvular heart disease varies depending on the underlying cause, age and health of the patient, and the degree of valvular damage or involvement. Whether one is living with valvular heart disease or recovering from it, the following are ways to minimize the chances of future problems:

- Inform all attending doctors and dentists about the disease.

WWW.BOOKBAZ.IR

- Be knowledgeable about the type of valvular heart disease.
- Take all prescribed medications faithfully in the correct amounts and at the proper times.
- Carry identification at all times that specifies specific antibiotic requirements.
- Call the doctor when any symptoms resembling an infection first appear.
- Perform daily hygiene of teeth and gums, including brushing and flossing.
- Take antibiotics before any surgeries or procedures that may cause bleeding.
- Visit the doctor on a regular basis, according to recommendations of the doctor.

Rheumatic fever

Patients with rheumatic heart disease face a lifetime of caution over contact with the same bacterium that caused the disease. Since it can cause inflammation of one or more organs or joints, complications can occur. The inflammation of the heart may subside without side effects. Permanent scarring of one or more heart valves is a possibility and may require surgery to repair or replace damaged valves. In severe cases, rheumatic fever can lead to death from heart failure.

Infective endocarditis

The prognosis for patients with infective endocarditis depends on the underlying heart disease and resulting complications. If the disease further damages heart valves, symptoms may occur for years after initial treatment. Sometimes, endocarditis can result in heart or renal failure. If untreated, it can be fatal.

Prevention

Certain measures can be taken to prevent some valvular disease. However, once valvular heart disease that results from congenital abnormality occurs, it may not be prevented. Steps can be taken to prevent further complications. Individuals should always get prompt medical treatment when a **sore throat** lingers for longer than 24 hours, especially if it involves a fever. A heart-healthy diet and lifestyle are also helpful for preventing further complications from valvular heart disease. The following is advised:

- Do not smoke tobacco products.
- Consume alcohol in moderation; no more than two drinks a day for men and a single drink a day for women.
- Eat a healthy and balanced diet that is low in salt and fat.

KEY TERMS

Congenital—A condition or defect present at birth.

Stenosis—An abnormal valve condition that is characterized by tightening or narrowing of the opening.

Streptococcal (*Streptococcus*)—A bacterium that causes infection in people. Its most commonly known strain causes the infection strep throat.

Throat culture—A test for strep throat that involves swabbing the back of the throat and sending the swab to a laboratory, which determines whether bacteria are present.

- Exercise regularly.
- Do not become overweight.
- If diabetic, control blood sugar levels.

Rheumatic fever

The best prevention for rheumatic fever is prompt and thorough treatment of any suspected streptococcal infection, particularly strep throat in children. A physician should check any sore throat with fever that persists for more than 24 hours. The physician will probably order a **throat culture**. Completion of the antibiotic treatment even after symptoms diminish is important to be certain the infection is eliminated.

Infective endocarditis

Individuals who are born with a defective heart valve, those with artificial (prosthetic) valves, and those who have had a valve scarred by rheumatic fever should use prescribed antibiotics by mouth before and after a dental procedure. These patients also may need to receive injected antibiotics prior to procedures involving the bladder, prostate, and pelvic organs.

Appetite suppressants

The drug associated with valvular heart disease, fen-phen, was removed from the market, so as long as people avoid obtaining this appetite suppression combination, they can prevent its negative effects.

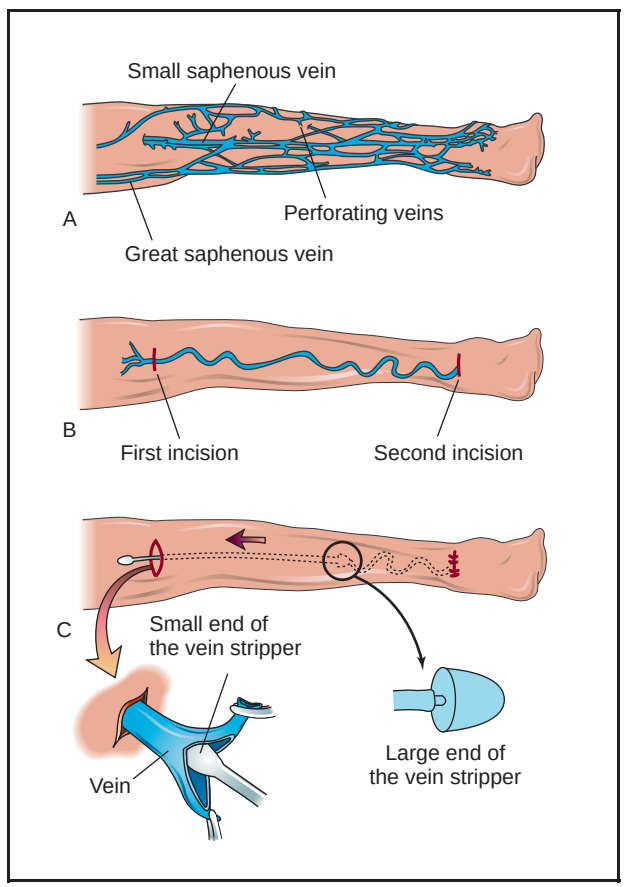
Varicose veins

Definition

Varicose veins are dilated, tortuous, elongated superficial veins that are usually seen in the legs.

Description

Varicose veins, also called varicosities, are seen most often in the legs, although they can be found in other parts of the body. Most often, they appear as lumpy, winding vessels just below the surface of the skin. There are three types of veins, superficial veins that are just beneath the surface of the skin, deep veins that are large blood vessels found deep inside muscles, and perforator veins that connect the superficial veins to the deep veins. The superficial veins are the blood vessels most often affected by varicose veins and are



Varicose veins may be surgically removed from the body when they are causing pain and when hemorrhaging or recurrent thrombosis appear. *(Illustration by Electronic Illustrators Group. © Cengage Learning®.)*

WWW.BOOKBAZ.IR

Varicose veins on a man's leg. *(Custom Medical Stock Photo, Inc.)*

the veins seen by eye when the varicose condition has developed.

The inside wall of veins has valves that open and close in response to the blood flow. When the left ventricle of the heart pushes blood out into the aorta, it produces the high pressure pulse of the heartbeat and pushes blood throughout the body. Between heartbeats, there is a period of low blood pressure. During the low pressure period, blood in the veins is affected by gravity and wants to flow downward. The valves in the veins prevent this from happening. Varicose veins start when one or more valves fail to close. The blood pressure in that section of vein increases, causing additional valves to fail. This allows blood to pool and stretch the veins, further weakening the walls of the veins. The walls of the affected veins lose their elasticity in response to increased blood pressure. As the vessels weaken, more and more valves are unable to close properly. The veins become larger and wider over time and begin to appear as lumpy, winding chains underneath the skin. Varicose veins can develop in the deep veins also. Varicose veins in the superficial veins are called primary varicosities, while varicose veins in the deep veins are called secondary varicosities.

Causes and symptoms

The predisposing causes of varicose veins are multiple, and lifestyle and hormonal factors play a role. Some families seem to have a higher incidence of varicose veins, indicating that there may be a genetic component to this disease. Varicose veins are progressive; as one section of the veins weakens, it causes increased pressure on adjacent sections of veins. These sections often develop varicosities. Varicose veins can appear following **pregnancy**, **thrombophlebitis**, congenital blood vessel weakness, or **obesity**, but is not limited to these conditions. **Edema** of the surrounding tissue, ankles, and calves, is not usually a complication of primary (superficial) varicose veins and, when seen, usually indicates that the deep veins may have varicosities or clots.

KEY TERMS

Congenital—Existing at or before birth; a condition that developed while the fetus was in utero or as a consequence of the birth process.

Edema—Swelling caused by a collection of fluid in a tissue or body cavity.

Hemorrhage—Bleeding from blood vessels.

Palpation—The process of examining a patient by touch.

Varicose veins are a common problem; approximately 15% of the adult population in the United States have varicose veins. Women have a much higher incidence of this disease than men. The symptoms can include aching, **pain**, itchiness, or burning sensations, especially when standing. In some cases, with chronically bad veins, there may be a brownish discoloration of the skin or **ulcers** (open sores) near the ankles. A condition that is frequently associated with varicose veins is spider-burst veins. Spider-burst veins are very small veins that are enlarged. They may be caused by back-pressure from varicose veins, but can be caused by other factors. They are frequently associated with pregnancy and there may be hormonal factors associated with their development. They are primarily of cosmetic concern and do not present any medical concerns.

Diagnosis

Varicose veins can usually be seen. In cases where varicose veins are suspected, but can not be seen, a physician may frequently detect them by palpation (pressing with the fingers). X rays or **ultrasound** tests can detect varicose veins in the deep and perforator veins and rule out **blood clots** in the deep veins.

Treatment

There is no cure for varicose veins. Treatment falls into two classes; relief of symptoms and removal of the

affected veins. Symptom relief includes such measures as wearing support stockings, which compress the veins and hold them in place. This keeps the veins from stretching and limits pain. Other measures are sitting down, using a footstool when sitting, avoiding standing for long periods of time, and raising the legs whenever possible. These measures work by reducing the blood pressure in leg veins. Prolonged standing allows the blood to collect under high pressure in the varicose veins. **Exercise**, such as walking, biking, and swimming, is beneficial. When the legs are active, the leg muscles help pump the blood in the veins. This limits the amount of blood that collects in the varicose veins and reduces some of the symptoms. These measures reduce symptoms, but do not stop the disease.

Surgery is used to remove varicose veins from the body. It is recommended for varicose veins that are causing pain or are very unsightly and when hemorrhaging or recurrent thrombosis appear. Surgery involves making an incision through the skin at both ends of the section of vein being removed. A flexible wire is inserted through one end and extended to the other. The wire is then withdrawn, pulling the vein out with it. This is called "stripping" and is the most common method to remove superficial varicose veins. As long as the deeper veins are still functioning properly, a person can live without some of the superficial veins. Because of this, stripped varicose veins are not replaced.

Injection therapy is an alternate therapy used to seal varicose veins. This prevents blood from entering the sealed sections of the vein. The veins remain in the body, but no longer carry blood. This procedure can be performed on an outpatient basis and does not require **anesthesia**. It is frequently used if people develop more varicose veins after surgery to remove the larger varicose veins and to seal spider-burst veins for people concerned about cosmetic appearance. Injection therapy is also called sclerotherapy. At one time, a method of injection therapy was used that did not have a good success rate. Veins did not seal properly and blood clots formed. Modern injection therapy is improved and has a much higher success rate.

Prognosis

Untreated varicose veins become increasingly large and more obvious with time. Surgical stripping of varicose veins is successful for most patients. Most do not develop new, large varicose veins following surgery. Surgery does not decrease a person's tendency to develop varicose veins. Varicose veins may develop in other locations after stripping.

Vascular disease

Definition

Vascular disease is a general term for any disease or blood disorder that occurs in the arteries and veins (along with their capillaries) that carry blood to and from the heart, in what together is called the vascular system (also the circulatory system) or the body's network of blood vessels. Medical researchers have identified many specific types of vascular disease. Two examples are peripheral artery disease and the many blood disorders such as those that relate to disorders of the blood to clot, what are generally termed blood-clotting disorders. Vascular disease can be quite serious, leading sometimes to physical disability, **amputation** of limbs, damage to the body's organ, and even death.

Description

The vascular system is composed of arteries and veins. Arteries carry oxygen-rich blood away from the heart, whereas veins return oxygen-depleted blood to the heart. Vascular disease can occur in either arteries or veins, although vascular disease in arteries is more common.

Arteriosclerosis and atherosclerosis are the most common causes of vascular disease. Arteriosclerosis is commonly called hardening of the arteries. The large and medium-sized arteries of the body have elastic, muscular walls. Whenever the heart contracts and pushes blood into the arteries, the walls of the artery expand slightly to accommodate the increased pressure of the blood. However, over many years, too much pressure can cause the artery walls to thicken and harden, losing their elasticity. This loss of elasticity is called arteriosclerosis.

Atherosclerosis is the build-up of plaque on the inside of the artery walls. Arterial plaque (different from dental plaque that builds up on teeth) is made up of fats, **cholesterol**, **calcium**, and bits of dead cells. Plaque can restrict the flow of blood. If blood flow is

WWW.BOOKBAZ.IR

restricted, the heart must work harder (exert more pressure) to push blood through the artery, and blood pressure rises. Plaque also can break off, causing damage to the artery wall. A blood clot may form where this happens. Bits of plaque and **blood clots** can form an **embolism**, which can travel through the vascular system with the potential to block a smaller artery and restrict or shut off the blood supply flowing through that artery. If blood supply to the heart is shut off, the individual has a **heart attack**. If blood supply is shut off in the internal carotid artery going to the brain or in any of the small vessels in the brain, the individual has a **stroke**. If the brain blockage is brief and resolves on its own with minimal damage, the incident is called a **transient ischemic attack** (TIA). Blood vessels in other parts of the body also may be blocked, with blockage most common in the blood vessels in the legs. Arteriosclerosis and atherosclerosis most often occur together, and these terms commonly are used interchangeably to indicate the presence of vascular disease.

Arteriosclerosis and atherosclerosis can lead to the following types of vascular disease:

- Hypertension (high blood pressure): the heart must use more force to pump blood through inflexible arteries and past obstructions in the arteries.
- Coronary artery disease (CAD): the coronary arteries that supply the heart are narrowed.
- Cerebrovascular disease, carotid artery disease, or stroke: a blood vessel to the brain is narrowed or blocked.
- Peripheral artery disease (PAD), also called peripheral vascular disease (PDV): blood vessels in other parts of the body than the heart, usually the legs, are narrowed or blocked. This disease is most common in people with diabetes.
- Renovascular disease: arteries to the kidney are narrowed.
- Peripheral aneurysms: a condition of the abdomen or behind the knee causes weak spots in the wall of an artery that bulge out and can burst. They may form where plaque breaks off the artery wall.

Types of vascular disease that are not directly related to atherosclerosis or arteriosclerosis include:

- Deep vein thrombosis develops from prolonged periods of inactivity that reduce circulation and allow blood to pool and clots to form in the interior (deep) veins of the legs.
- Pulmonary embolism occurs when a blood clot breaks off and travels to the artery supplying the lungs. Pulmonary embolisms that completely block the artery to the lung are fatal.
- Chronic venous insufficiency occurs when a blood clot prevents enough blood from flowing back to the heart.
- Thoracic outlet syndrome (TOS) can be caused by compression of a vein or artery going to the arm. Venous compression often is caused by repetitive, energetic use of the arm (e.g., such as the pitching motion of a baseball pitcher), and artery compression often occurs in individuals who were born with a small extra rib. Nerves can also be compressed in TOS.
- Certain disorders, such as thrombocythemia or polycythemia vera, cause blood to clot too easily, increasing the risk of embolism formation.

Risk factors

Although there are a number of different vascular diseases, most have risk factors in common. An increased risk of developing vascular disease occurs in individuals who have the following traits:

- have any condition that affects the blood vessels or the heart
- are obese
- use tobacco
- have high blood pressure
- have high cholesterol and triglyceride levels
- get little exercise
- are injured or have an illness over a long period
- eat a diet high in saturated fats and low in fiber
- have either type 1 or type 2 diabetes, especially if poorly controlled
- have a family history of heart or vascular disease
- experience prolonged immobility, such as during a hospital stay after surgery, or extended periods of sitting or standing still in daily life
- are pregnant

Smoking tobacco products is a major risk factor for vascular disease.

Demographics

Vascular disease is common, especially in people over the age of 50 years. The exact number of people with vascular disease is difficult to estimate, as many vascular diseases show no symptoms until they reach an advanced stage. According to the American Stroke Association, about 795,000 Americans have new or recurrent strokes each year—strokes often occur as a result of vascular disease. Of that number, over 137,000

people die each year from strokes. Specifically, one of the leading causes of death in the United States is stroke. According to the University of Maryland Medical Center, about 20 to 30 million Americans are at risk for vascular disease.

Vascular disease is more common in men than it is in women and appears in men at an earlier age. Researchers believe that the female hormone estrogen provides a protective effect until women reach the age of **menopause** at about age 50. Further, according to the American Vascular Association, vascular disease causes nearly as much death and disability as does **heart disease** and more than cancer.

The following statistics of various disorders within vascular disease come from the Vascular Disease Foundation:

- About 200,000 Americans are diagnosed with abdominal aortic aneurysm each year. Of that number, almost 15,000 of them could die from it if the aorta is not treated before it ruptures.
- Approximately one in three people 70 years of age and older in the United States have peripheral artery disease. It affects from eight to 10 million Americans each year.
- Stroke is the fourth leading cause of death in the United States and is the leading cause of disability in the country.
- Dangerous blood clots form in the legs of over 2.5 million Americans each year.
- Deep venous thrombosis occurs in about one out of 20 people over a lifetime.
- About one million Americans have leg ulcers caused by diseased veins.
- Over 24 million people in the United States have varicose veins.

Internationally, vascular disease is highest in regions where people eat a Western diet high in animal fats and calories and low in fiber (e.g., Northern Europe). In cultures in Africa where the diet is low in animal products, low in calories, and high in whole grains, the prevalence of vascular disease is low.

Causes and symptoms

Poor diet resulting in high levels of cholesterol and fats in the blood, lack of **exercise**, **aging**, uncontrolled **hypertension**, and uncontrolled diabetes lead to the development of atherosclerosis and arteriosclerosis. These, in turn, cause other vascular diseases. Some vascular problems have a hereditary component (e.g., TOS, blood clotting diseases).

Atherosclerosis and arteriosclerosis develop gradually with no symptoms until the artery is so rigid and narrow that not enough blood can flow through it to meet the needs of the tissue it supplies. At this point, **pain** is the most common symptom. Clogged coronary arteries can cause chest pain (**angina**) and complete blockage causes a heart attack (myocardial infarction). Clogged arteries supplying the brain can lead to diminished mental function. Complete blockage of the blood supply can result in sudden numbness and weakness in the face, arm, or leg. Speech and coordination may be affected. If these events are brief and there is no lasting damage, the individual is said to have had a transient ischemic attack or TIA, or warning stroke. If damage is permanent, the individual is said to have had a stroke or cerebrovascular accident (CVA). **Peripheral vascular disease** usually results in pain. If blockage occurs in the legs, the individual will have pain when walking and possible swelling. Sores on the legs and feet will be slow to heal. Blockage of the arteries leading to the penis can cause **erectile dysfunction**.

Diagnosis

Certain people are at high risk for vascular disease. The people with the following conditions or lifestyles should be screened:

- diabetes
- family history of circulatory or atherosclerotic problems
- high blood pressure
- high blood cholesterol
- use of tobacco products

Diagnosis of vascular disease may occur during a routine **physical examination** or after the individual complains of symptoms.

Examination

Diagnosis begins with a complete physical examination and medical history. The doctor may notice abnormally high blood pressure or a weak pulse below the area of a blockage in an artery. By listening to the arteries in the neck, the doctor may be able to hear abnormal whooshing sounds (bruits). These sounds are caused by blood flowing around a blockage. The doctor also will look for signs of poor wound healing in the arms, legs, and feet, especially if the patient has diabetes.

Tests

Blood tests are done as part of a routine physical. Cholesterol, triglyceride, and blood sugar (blood glucose)

WWW.BOOKBAZ.IR

levels are checked. A urine test checks for protein in the urine, which indicates a problem with kidney function.

If blockage of an artery is suspected, a series of noninvasive tests can be performed to located the blockage and estimate its size. These include:

- Doppler ultrasound, a standard diagnostic test for blood clots in the vascular system. An ultrasound wand applied over the area of the suspected blockage uses high-frequency sound waves to measure the speed at which the blood moves through the artery. Movement at an abnormal speed indicates a blockage.
- Ankle-brachial index, a test to determine if there is a narrowing of arteries in the legs or feet. First, blood pressure is taken in the normal way in the arm. Next, blood pressure is taken in the ankle. In a healthy person, the systolic pressure (the top number in a blood pressure reading) in both places will be approximately equal. If systolic pressure is lower in the ankle reading, this suggests the individual has PAD in the leg.
- Electrocardiogram (ECG), for which electrodes are placed on the chest to measure the electrical activity of the heart. If an ECG is done while individuals are walking on a treadmill, it is called a stress test. The results of this test can be used to help determine the health of the arteries supplying blood to the heart.

Procedures

When an artery blockage has been found, the doctor may perform an angiogram to determine its exact size and location. A special dye is injected into the arteries that make them visible on x-ray images. From this, the doctor can pinpoint the location and size of the blockage(s). This test often is done before surgery to help guide the surgical procedure.

Treatment

Mild to moderate vascular disease usually is treated with a combination of lifestyle changes and drug therapy. If this fails or if vascular disease is severe, surgery may be required.

Home remedies and lifestyle changes

An important first-line treatment for mild to moderate vascular disease involves lifestyle changes. These can be very effective. They include:

- losing weight if necessary and maintaining a healthy weight
- stopping the use of tobacco products, especially smoking
- avoiding alcohol or consuming alcohol in moderation
- exercising moderately but regularly (five days a week)
- eating a diet low in animal fats and sweets and high in fresh fruits, vegetables, and fiber
- controlling high blood pressure through salt (sodium) restriction, exercise, and medications as necessary
- controlling diabetes through exercise, diet, and medication as necessary by monitoring blood glucose levels regularly

Drugs

When lifestyle changes are not enough to control vascular disease, drug therapy may be added to the program. These drugs normally are taken long term and should not be stopped without consulting a doctor. Drugs may include:

- cholesterol-lowering drugs such as simvastin (Zocor) or atorvastatin (Lipitor)
- anti-platelet drugs such as aspirin or cloplidgrel (Plavix) to reduce the chance of platelets forming clumps in the blood
- anticoagulant drugs such as warfarin (Coumadin) to keep blood from clotting
- drugs to lower blood pressure (antihypertensive drugs)

Surgery

When lifestyle changes and drugs are not adequate or if blood vessel blockage is severe, surgical procedures may be used to open the blood vessel. These include:

- Balloon angioplasty. In this procedure, a thin wire with a deflated balloon at the tip is moved through an artery until it reaches the blockage. The balloon is then inflated so that the obstructing plaque is pressed against the artery wall and the vessel is made wider. Often a short mesh tube called a stent is placed at the site of the blockage to keep the blood vessel open.
- Endartectomy or atherectomy. These are surgical procedures to ream out blood vessels. This is sometimes called Rotorooter surgery. Endartectomy is often performed on the carotid artery.
- Bypass surgery. A section of blocked vessel is surgically removed and replaced with blood vessel taken from elsewhere in the body.
- Thrombolytic therapy. This uses a drug that breaks up blood clots. The drug is surgically delivered to the spot in the artery where the clot exists.

KEY TERMS

Aneurysm—An abnormal bulge of an artery that can rupture leading to hemorrhage.

Angiogram—An x-ray (radiographic) study of the blood vessels, which uses a radiopaque substance, or contrast medium, to make the blood vessels visible under a x-ray scan.

Angioplasty—A technique used for treating blocked coronary arteries by inserting a catheter with a tiny balloon at the tip into the artery and then inflating it.

Arteriosclerosis—A chronic condition characterized by thickening and hardening of the arteries and the build-up of plaque on the arterial walls. Arteriosclerosis can slow or impair blood circulation.

Atherosclerosis—A chronic condition characterized by plaque formed on the arterial walls. Atherosclerosis can slow or impair blood circulation.

Balloon angioplasty—A surgical procedure to reopen a partially blocked artery so that blood can flow through it again at a normal rate. A tiny tube (catheter) is threaded through blood vessels to the point of the blockage. The catheter contains a balloon that is then expanded to stretch and open the artery.

Carotid artery—An artery located in the neck. There are two on each side of the neck. The internal carotid artery carries blood to the brain, whereas the external carotid artery carries blood to skin and muscles of the face.

Cholesterol—A waxy substance made by the liver and also acquired through diet. High levels in the blood may increase the risk of cardiovascular disease.

Coronary arteries—The first arteries to branch off the aorta (the large artery leaving the heart). The coronary arteries surround the heart like a crown, coming out of the aorta, arching down over the top of the heart, dividing into two branches, and taking oxygen-rich blood to the heart muscle. Blockage of these arteries can cause insufficient blood flow to the heart or a heart attack.

Coronary artery disease (CAD)—Also called atherosclerosis, a build-up of fatty matter and debris in the coronary artery wall that causes narrowing of the artery.

Electrocardiogram (ECG, EKG)—A test that records the electrical activity of the heart using small electrode patches attached to the skin on the chest.

Embolism—A blood clot, air bubble, or clot of foreign material that travels through and blocks the flow of blood in an artery. When blood supply to a tissue or organ is blocked by an embolism, infarction (death of the tissue the artery feeds) occurs. Without immediate and appropriate treatment, an embolism can be fatal.

Stent—A device made of expandable, metal mesh that is placed (by using a balloon catheter) at the site of a narrowing artery; the stent stays in place to keep the artery open.

Stress test—A test that involves an electrocardiogram during rest and exercise to determine how the heart responds to stress.

Stroke—Irreversible damage to the brain caused by insufficient blood flow to the brain as the result of a blocked artery. Damage can include loss of speech or vision, paralysis, cognitive impairment, and death.

Triglycerides—A type of fat found in the blood. High levels of triglycerides can increase the risk of coronary artery disease.

Type 1 diabetes—A chronic immune system disorder in which the pancreas does not produce sufficient amounts of insulin, a hormone that enables cells to use glucose for energy. Also called juvenile diabetes, it must be treated with insulin injections.

Type 2 diabetes—Formerly called adult-onset diabetes. In this form of diabetes, the pancreas either does not make enough insulin or cells become insulin resistant and do not use insulin efficiently.

Ultrasound—A technique that uses high-frequency sound waves to create a visual image (a sonogram) of soft tissues.

Prognosis

The progression of vascular disease often is silent and gradual until a dramatic event such as a stroke or heart attack occurs. Vascular disease is highly treatable—when recognized early—through lifestyle changes and drug therapy. When recognized late, surgery may be required. If unrecognized, vascular disease can be fatal.

Prevention

Prevention cannot be totally successful, but the condition can be minimized with regards to its risk by

WWW.BOOKBAZ.IR

living a healthy life, including a heart-healthy diet, exercise, not smoking tobacco products, a healthy weight, and control of blood pressure and diabetes. Prevention needs to begin at as early an age as possible because vascular disease normally shows no symptoms until it is advanced. However, making these changes, even after vascular disease has developed can reverse or slow its progression.

Vascular headache *see* **Migraine headache**

Vascular surgery

Definition

Vascular surgery is the treatment of surgery on patients diagnosed with diseases of the arterial, venous, and lymphatic systems (excluding the intracranial and coronary arteries).

Purpose

Vascular surgery is indicated when a patient has **vascular disease** that cannot be treated by less invasive, nonsurgical treatments. The purpose of vascular surgery is to treat vascular diseases, which are diseases of the arteries and veins. Arterial disease is a condition in which **blood clots**, arteriosclerosis, and other vascular conditions occur in the arteries. Venous disease involves problems that occur in the veins. Some vascular conditions occur only in arteries, others occur only in the veins, and some affect both veins and arteries.

Demographics

As people age, vascular diseases are very common. Since they rarely cause symptoms in the early stages, many people do not realize that they suffer from these diseases. A large percentage of the 10 million people in the United States who may have **peripheral vascular disease** (PVD) or peripheral artery disease (PAD) are males. In the majority of cases, the blockage is caused by one or more blood clots that travel to the lungs from another part of the body. Factors that increase the chances of vascular disease include:

- increasing age (which results in a loss of elasticity in the veins and their valves)
- a family history of heart or vascular disease
- illness or injury
- pregnancy
- prolonged periods of inactivity sitting, standing, or bed rest
- smoking
- obesity
- hypertension, diabetes, high cholesterol, or other conditions that affect the health of the cardiovascular system
- lack of exercise

Description

Vascular surgery involves techniques relating to endovascular surgeries, including balloon **angioplasty** and/or stenting, aortic and peripheral vascular endovascular stent/graft placement, thrombolysis, and other adjuncts for vascular reconstruction.

The vascular system is the network of blood vessels that circulate blood to and from the heart and lungs. The circulatory system (made up of the heart, arteries, veins, capillaries, and the circulating blood) provides nourishment to the body's cells and removes their waste. The arteries carry oxygenated blood from the heart to the cells. The veins return the blood from the cells back to the lungs for reoxygenation and recirculation by the heart. The aorta is the largest artery leaving the heart; it then subdivides into smaller arteries going to every part of the body. The arteries, as they narrow, are connected to smaller vessels called capillaries. In these capillaries, oxygen and nutrients are released from the blood into the cells, and cellular wastes are collected for the return trip. The capillaries then connect to veins, which return the blood back to the heart.

The aorta stems from the heart, arches upward, and then continues down through the chest (thorax) and the abdomen. The iliac arteries, which branch out from the aorta, provide blood to the pelvis and legs. The thoracic section of the aorta supplies blood to the upper body, as it continues through the chest. The abdominal section of the aorta, which supplies blood to the lower body, continues through the abdomen.

Vascular diseases are usually caused by conditions that clog or weaken blood vessels, or damage valves that control the flow of blood in and out of the veins, thus robbing them of vital blood nutrients and oxygen. A few common diseases affecting the arteries are peripheral vascular disease (PVD), carotid artery disease, and aortic aneurysms.

Surgery is used to treat specific diseased arteries, such as atherosclerosis, to help prevent strokes or heart attacks, improve or relieve **angina** or **hypertension**, remove aneurysms, improve claudication, and save legs that would otherwise have to be amputated. The choices involve repairing the artery, bypassing it, or replacing it.

As people age, atherosclerosis, commonly called hardening of the arteries, occurs with the constant passage of blood through the arteries. It can take on a number of forms, of which atherosclerosis (hardening of the innermost portion) is the most common. This occurs when fatty material containing **cholesterol** or **calcium** (plaque) is deposited on the innermost layer of the artery. This causes a narrowing of the inside diameter of the blood vessel. Eventually, the artery becomes so narrow that a blood clot (thrombus) forms, and blocks blood flow to an entire portion of the body. This condition is called PVD, or peripheral arterial disease. In another form of atherosclerosis, a rough area or ulcer forms in the diseased interior of the artery. Blood clots then tend to develop on this ulcer, break off, and travel further along, forming a blockage where the arteries get narrower. A blockage resulting from a clot formed elsewhere in the body is called an **embolism**.

People who have few areas affected by PVD may be treated with angioplasty by opening up the blood vessel with a balloon placed on the end of a catheter. A stent is often used with angioplasty to help keep the artery open. The type of surgery used to treat PVD is based upon the size and location of the damaged artery. The surgery techniques used for severe PVD include:

- Bypass surgery is preferred for people who have many areas of blockage or a long, continuous blockage.

WWW.BOOKBAZ.IR

KEY TERMS

Abdominal aortic aneurysm—Occurs when an area in the aorta (the main artery of the heart) is weakened and bulges like a balloon. The abdominal section of the aorta supplies blood to the lower body.

Aneurysm—A weakening of the artery wall, due to atherosclerosis, causing a bulge that can rupture and lead to thrombosis or embolism.

Angiography or angiogram—An x-ray exam of the arteries and veins (blood vessels) to diagnose blockages and other blood vessel problems.

Ankle-brachial index (ABI) test—A means of checking the blood pressure in the arms and ankles using a regular blood pressure cuff and a special ultrasound stethoscope (Doppler). The pressure in the ankle is compared to the pressure in the arm.

Aorta—A large, elastic artery beginning at the upper part of the left ventricle of the heart that becomes the main trunk of the arterial system.

Aortic aneurysms—Occurs when an area in the aorta (the main artery of the heart) is weakened and bulges like a balloon.

Arteriogram—An x-ray picture of an artery achieved by injecting an opaque dye with a needle or tube into the affected artery.

Artery—A blood vessel conveying blood in a direction away from the heart.

Atherosclerosis—A form of arteriosclerosis affecting the innermost area of the artery; a series of calcified deposits that can close down the vessel.

Bruit—A roaring sound created by a partially blocked artery.

Capillary—Smallest extremity of the arterial vessel, where oxygen and nutrients are released from the blood into the cells, and cellular waste is collected.

Carotid artery—Major artery leading to the brain, blockages of which can cause temporary or permanent strokes.

Carotid artery disease—A condition in which the arteries in the neck that supply blood to the brain become clogged, making a stroke possible.

Carotid endarterectomy—A surgical technique for removing intra-arterial obstructions of the internal carotid artery.

Cerebral aneurysm—The dilation, bulging, or ballooning out of part of the wall of a vein or artery in the brain.

Cholesterol—An abundant fatty substance in animal tissues. High levels in the diet are a contributing factor in causing atherosclerosis.

Claudication—Attacks of lameness or pain chiefly in the calf muscles, brought on by walking, because of a lack of oxygen reaching the muscle.

Collaterals—Alternate pathways for arterial blood.

Computed tomography (CT) scan—An imaging technique that produces three-dimensional pictures of organs and structures inside the body using a 360° x-ray beam.

Coronary—Of or relating to the heart.

Doppler ultrasound—A diagnostic procedure that uses sound waves to evaluate blood flow through major arteries and veins.

- Aortobifemoral bypass is used for PVD affecting the major abdominal artery (aorta) and the large arteries that branch off of it.
- In a technique called thromboendarterectomy, the inner diseased layers of the artery are removed, leaving the relatively normal outer coats of the artery.
- Resection involves a technique to remove a diseased artery following an aneurysm; a bypass is created with a synthetic graft.
- In a bypass graft, a vein graft from another part of the body or a graft made from artificial material is used to create a detour around a blocked artery.
- Tibioperoneal bypass is used for PVD affecting the arteries in the lower leg or foot.
- Femoral-femoral bypass is a procedure to bypass occlusive disease in the unilateral common or external iliac artery.
- Femoropopliteal (fem-pop) bypass surgery is used for PVD affecting the arteries above and below the knee.
- Embolectomy is a technique in which an embolic clot on the wall of the artery is removed, using an inflatable balloon catheter.
- Thrombectomy is a technique in which a balloon catheter is inserted into the affected artery beyond a blood clot. The balloon is then inflated and pulled back, bringing the clot with it.

An aneurysm occurs when weakened blood vessels bulge like balloons as blood flows through them. Once

Embolism—Obstruction or closure of a vessel by a transported clot of foreign matter.

Endovascular grafting—A procedure that involves the insertion of a delivery catheter through a groin artery into the abdominal aorta under fluoroscopic guidance.

Intracranial—Existing or occurring within the cranium; affecting or involving intracranial structures.

Lower extremity amputation—The cutting off of a leg.

Lymphangiography—Injection of dye into lymphatic vessels followed by x rays of the area. It is a difficult procedure, as it requires surgical isolation of the lymph vessels to be injected.

Lymphoscintigraphy—A technique in which a radioactive substance that concentrates in the lymphatic vessels is injected into the affected tissue and mapped using a gamma camera, which images the location of the radioactive tracer.

Magnetic resonance imaging (MRI)—A noninvasive diagnostic technique that produces computerized images of internal body tissues and is based on nuclear magnetic resonance of atoms within the body induced by the application of radio waves.

Plethysmography—A test in which a patient sits inside a booth called a plethysmograph and breathes through a mouthpiece, while pressure and air flow measurements are collected to measure the total lung volume.

Pulmonary embolism—A blocked artery in the lung.

Renal artery aneurysm—An aneurysm relating to, involving, or located in the region of the kidneys.

Thoracic aortic aneurysm—An aneurysm that occurs when an area in the thoracic section of the aorta (the chest) is weakened and bulges like a balloon. The thoracic section supplies blood to the upper body.

Thrombolysis—A treatment that opens up blood flow and may prevent permanent damage to the blood vessels.

Thrombosis—The formation or presence of a blood clot within a blood vessel.

Thrombus—A blood clot that may form in a blood vessel or in one of the cavities of the heart.

Ulcer—A lesion or rough spot formed on the surface of an artery.

Ultrasound scan—A scan that produces images of arteries on a screen and is used to evaluate the blood flow, locate blockages, and measure the size of the artery.

Varicose veins—Twisted, enlarged veins near the surface of the skin, which develop most commonly in the legs and ankles.

Vascular—Relating to the blood vessels.

Vasculogenic erectile dysfunction—The inability to attain or sustain an erection satisfactory for coitus, due to atherosclerotic disease of penile arteries, inadequate impedance of venous outflow (venous leaks), or a combination of both.

Venous stasis disease—A condition in which there is pooling of blood in the lower leg veins that may cause swelling and tissue damage, and lead to painful sores or ulcers.

they have grown to a certain size, there is a risk of rupture and life-threatening bleeding. There are two types of aortic aneurysms: abdominal **aortic aneurysm** (AAA) and thoracic aortic aneurysm. This classification is based on where the aneurysm occurs along the aorta. Aneurysms are more common in the abdominal section of the aorta than the thoracic section.

Most blood clots originate in the legs, but they can also form in the veins of arms, the right side of the heart, or even at the tip of a catheter placed in a vein. Venous disease conditions that usually occur in the veins of the legs include:

- varicose veins
- phlebitis
- venous stasis disease
- deep vein thrombosis (DVT)
- claudication
- blood clots

Carotid artery disease is a condition in which the arteries in the neck that supply blood to the brain become clogged; this condition can cause a **stroke**.

Lymphatic obstruction involves blockage of the lymph vessels, which drain fluid from tissues throughout the body and allow immune cells to travel where they are needed. Some of the causes of lymphatic obstruction (also known as swelling of the lymph passages), include infections such as chronic **cellulitis**, or

WWW.BOOKBAZ.IR

parasitic infections such as **filariasis**, **trauma**, tumors, certain surgeries including **mastectomy**, and **radiation therapy**. There are rare forms of congenital **lymphedema** that probably result from abnormalities in the development of the lymphatic vessels. Most patients with lymphedema will not need surgery, as the symptoms are usually managed by other techniques. Surgical therapy for lymphedema includes removal of tissue containing abnormal lymphatics, and less commonly, transplant of tissue from areas with normal lymphatic tissues to areas with abnormal lymphatic drainage. In rare cases, bypass of abnormal lymphatic tissue is attempted, sometimes using vein grafts.

Other examples of vascular surgery include:

- cerebral aneurysm
- acute arterial and graft occlusion
- carotid endarterectomy
- endovascular grafting
- vasculogenic erectile dysfunction
- renal artery aneurysm
- surgery on varicose veins
- lower extremity amputation

Diagnosis

In order for patients to be diagnosed with a vascular disease, they must be clinically evaluated by a vascular surgeon, which includes a history and **physical examination**. A vascular surgeon also treats vascular disorders by non-operative means, including drug therapy and risk factor management.

The symptoms produced by atherosclerosis, thrombosis, embolisms, or aneurysms depend on the particular artery affected. These conditions can sometimes cause **pain**, but often there are no symptoms at all.

A physician has many ways of feeling, hearing, measuring, and even seeing arterial blockages. Many arteries in the body can be felt or palpated. A doctor can feel for a pulse in an area that the doctor believes is afflicted. Usually, the more advanced the arteriosclerosis, the less pulse in a given area.

As the artery becomes blocked, it can cause a noise very much like water roaring over rocky rapids. The physician can listen to this noise (bruit) directly, or can use special amplification systems to hear the noise.

There are other tests that can be done to determine if arterial blood flow is normal, including:

- ankle-brachial index (ABI) test
- arteriogram
- segmental pressure test
- ultrasound scan
- magnetic resonance imaging (MRI)
- computed tomography (CT) scan
- angiography
- lymphangiography
- lymphoscintigraphy
- plethysmography
- duplex ultrasound scanning

There may be no symptoms of vascular disease caused by blood clots until the clot grows large enough to block the flow of blood through the vein. Symptoms that may come on suddenly include:

- pain
- sudden swelling in the affected limb
- reddish blue discoloration
- enlargement of the superficial veins
- skin that is warm to the touch

The physician will probably do an evaluation of all organ systems, including the heart, lungs, circulatory system, kidneys, and the gastrointestinal system. The decision whether to have surgery or not is based on the outcome of these evaluations.

Preparation

For high-risk patients undergoing vascular surgery, research has shown that taking oral beta-blockers one to two weeks before surgery and continuing for at least two weeks after the operation can significantly reduce the chance of dying or having a **heart attack**. Scientists suspect that the drug improves oxygen balance in the wall of the heart and stabilizes plaques in the arteries.

Aftercare

The length of time in intensive care and hospitalization will vary with each surgery, as will the recovery time, depending on numerous factors. Because surgery for an AAA is more serious, the patient can expect to be in intensive care for 24 hours, and in the hospital for five to 10 days, providing the patient was healthy and had a smooth operative and postoperative course. The hospital stay will likely increase if there are complications. It may take as long as six months to fully recover from surgery for an AAA.

Living a heart-healthy lifestyle is the best way of preventing and controlling vascular disease: quit **smoking**; eat nutritious foods low in fat; **exercise**; maintain a healthy weight; and control risk factors such as high blood pressure, high cholesterol, diabetes,

hypertension, and other factors that contribute to vascular disease.

Medications that may be used to treat PVD include:

- aspirin and other antiplatelet medications to treat leg pain
- statins to lower cholesterol levels
- medications to control high blood pressure
- medications to control diabetes
- anticoagulants (these are rarely, but not generally, used to treat PVD unless the person is at an increased risk for forming blood clots)

Risks

All surgeries carry some risks. There is a risk of infection whenever incisions are required. Operations in the chest or those that involve major blood vessels carry a higher risk of complications. Patients that have high blood pressure, chronic lung or **kidney disease**, or other illnesses are at greater risk of complications during and after surgery. Other risks of vascular surgery include:

- bleeding
- failed or blocked grafts
- heart attack or stroke
- smoking
- leg swelling if a leg vein is used
- people over 65 years are at greater risk for brain impairment after major surgery
- the more damaged the circulatory system is before surgery, the higher susceptibility to mental decline after vascular surgery
- impotence

Patients should discuss risks with their surgeon after careful review of their medical history and a physical examination.

Results

The success rate for vascular surgery varies depending on a number of factors that may influence the decision on whether to have surgery or not, as well as the results.

The chance that an aneurysm will rupture generally increases with the size of the aneurysm; AAAs smaller than 1.6 in. (4 cm) in diameter have up to a 2% risk of rupture, while ones larger than 2 in. (5 cm) in diameter have a 22% risk of rupture within two years.

Arterial bypass surgery and peripheral bypass surgery have very good success rates. Most of those who undergo AAA surgery recover well, except in the case of a rupture. Most patients who have a ruptured aortic aneurysm die due to excessive, rapid blood loss.

Surgical therapy for lymphedema has met with limited success, and requires significant experience and technical expertise.

Morbidity and mortality rates

Peripheral vascular disease affects 10 million people in the United States, including 5% of those over 50. Only a quarter of PVD sufferers are receiving treatment. More than two million people in the United States develop DVT each year. More than 650,000 Americans experience a **pulmonary embolism** every year. Of those, approximately 200,000 people die from the condition.

Alternatives

There a few alternatives to treating vascular disease, although extensive research has not been done. **Acupuncture** is used to aid in hypertension and **chelation therapy** is thought to stabilize the effects of vascular disease. The focus should be on maintaining a proper diet and being aware of a family history of vascular disease so as to catch it as early as possible.

Health care team roles

A vascular surgeon performs the procedure in a hospital operating room. Applicants for residency training in vascular surgery must have successfully completed a **general surgery** residency and be eligible for the board examination in general surgery. An individual must meet the standards set by the Vascular Surgery Board of the American Board of Surgery for cognitive knowledge and hypothetical case management. At the completion of a vascular surgery residency, both a written and oral examination must be completed before certification. A vascular surgeon is required to undergo periodic written reexamination.

REVISED BY LAURA JEAN CATALDO, RN, EdD

Vasculitis

Definition

Vasculitis refers to a varied group of disorders which all share a common underlying problem of inflammation of a blood vessel or blood vessels. The inflammation may affect any size blood vessel, anywhere in the body. It may affect either arteries and/or veins. The inflammation may be focal, meaning that it affects a single location within a vessel, or it may be widespread, with areas of inflammation scattered throughout a particular organ or tissue, or even affecting more than one organ system in the body.

Description

Inflammation is a process which occurs when the immune system of the body responds to either an

This person's legs are afflicted with leukocytoblastic vasculitis, a condition in which a blood or lymph vessel becomes inflamed. *(Custom Medical Stock Photo, Inc.)*

injury or a foreign invader (virus, bacteria, or fungi). The immune system response involves sending a variety of cells and chemicals to the area in question. Inflammation causes blood vessels in the area to leak, causing swelling. The inflamed area becomes red, hot to the touch, and tender.

Antibodies are immune cells which recognize and bind to specific markers (called antigens) on other cells (including bacteria and viruses). These antibody-antigen complexes can then stimulate the immune system to send a variety of other cells and chemicals involved in inflammation to their specific location.

Some researchers believe that the damaging process of vasculitis is kicked off by such antibody-antigen complexes. These complexes are deposited along the walls of the blood vessels. The resulting inflow of immune cells and chemicals causes inflammation within the blood vessels.

The type of disease caused by vasculitis varies depending on a number of factors:

- the organ system or tissue in which the vasculitis occurs
- the specific type of inflammatory response provoked
- whether the affected vessels are veins (which bring blood to the heart) or arteries (which carry blood and oxygen from the heart to the organs and tissues)
- the degree to which blood flow within the affected vessel is reduced

Causes and symptoms

Some types of vasculitis appear to be due to a type of allergic response to a specific substance (for example, a drug). Other types of vasculitis have no identifiable initiating event. Furthermore, researchers have not been able to consistently identify antibody-antigen complexes in all of the types of diseases caused by vasculitis. The types of antigens responsible for the initial immune response have often gone unidentified as well. Furthermore, not all people with such complexes deposited along the blood vessels go on to develop vasculitis. Some researchers believe that, in addition to the presence of immune complexes, individuals must have some other characteristics which make them susceptible to vasculitis. Many questions have yet to be answered to totally explain the development these diseases.

Symptoms

Symptoms of vasculitis depend on the severity of the inflammation and the organ system or systems affected. Some types of vasculitis are so mild that the only symptoms noted are small reddish-purple dots (called petechiae) on the skin due to tiny amounts of blood seeping out of leaky blood vessels. In more widespread types of vasculitis, the patient may have general symptoms of illness, including **fever**, achy muscles and joints, decreased appetite, weight loss, and loss of energy. The organ systems affected by vasculitis may include:

- The skin. Rashes, bumps under the skin, petechiae, larger reddish-purple circles (purpura), or bruising (ecchymoses) may appear. Areas of skin totally deprived of blood flow, and therefore of oxygen, may die, resulting in blackened areas of gangrene.
- The joints. In addition to joint pain, the joints themselves may become inflamed, resulting in arthritis.
- Brain and nervous system. Inflammation of the blood vessels in the brain can cause headaches, changes in personality, confusion, and seizures. If an area of the brain becomes totally deprived of oxygen, a stroke occurs. A stroke means that an area of brain tissue is either severely injured or completely dead from lack of oxygen. This may leave the individual with a permanent disability. If the vessels that lead to the eyes are affected, vision may become seriously disturbed. Nerves in the arms and legs may result in painful tingling sensations, loss of feeling, and weakness.
- Gastrointestinal system. Patients may have significant abdominal pain, vomiting, and diarrhea. If blood flow is completely cut off to an area of intestine, that part of the intestine will die off. The liver may be affected.
- Heart. This is an extremely serious type of vasculitis. The arteries of the heart (coronary arteries) may develop weakened areas, called aneurysms. The heart muscle itself may become inflamed and enlarged. With oxygen deprivation of the heart muscle, the individual may suffer a heart attack.
- Lungs. The patient may experience shortness of breath with chest pain, and may cough up blood. There may be wheezing.
- Kidney. Changes in the arteries of the kidney may result in high blood pressure. The kidneys may become increasingly unable to appropriately filter the blood, and kidney failure may occur.

WWW.BOOKBAZ.IR

Specific diseases

Multiple types of disease are associated with vasculitis. Many autoimmune diseases have vasculitis as one of their complications. These include **systemic lupus erythematosus**, **rheumatoid arthritis**, **scleroderma**, and **polymyositis**. Other types of diseases which have vasculitis as their major manifestations include:

- Polyarteritis nodosa. This is an extremely serious, systemic (affecting systems throughout the body) form of vasculitis. Small and medium arteries are involved, and the inflammation is so severe that the walls of the arteries may be destroyed. Any organ system, or multiple organ systems, may be affected. The most serious effects include kidney failure, complications involving the heart, gastrointestinal problems, and high blood pressure.
- Kawasaki's disease is an acute disease which primarily strikes young children. Fever and skin manifestations occur in all patients. While most patients recover completely, a few patients suffer from vasculitis in the heart. This is frequently fatal.
- Henoch-Schonlein purpura. While this frequently occurs in children, adults may also be affected. This disease tends to affect the skin, joints, gastrointestinal tract, and kidneys.
- Serum sickness occurs when an individual reacts to a component of a drug, for example penicillin. Symptoms of this are often confined to the skin, although fevers, joint pain, and swelling of lymph nodes may also occur.
- Temporal arteritis (also called giant cell arteritis) tends to involve arteries which branch off the major artery that leads to the head, called the carotid. An artery which feeds tissues in the area of the temple (the temporal artery) is often affected. Severe headaches are the most classic symptom. Other symptoms include fatigue, loss of appetite and then weight, fever, heavy sweating, joint pain, and pain in the muscles of the neck, shoulders, and back. If the vasculitis includes arteries which supply the eye, serious visual disturbance or even blindness may result.
- Takayasu's arteritis affects the aorta (the very large main artery that exits the heart and receives all of the blood to be delivered throughout the body), and arteries which branch off of the aorta. Initial symptoms include fatigue, fever, sweating at night, joint pain, and loss of appetite and weight. Every organ may be affected by this disease. A common sign of this disease is the inability to feel the pulse in any of the usual locations (the pulse is the regular, rhythmic sensation one can feel with a finger over an artery, for example in the wrist, which represents the beating of the heart and the regular flow of blood).
- Wegener's granulomatosis: This disease exerts its most serious effects on the respiratory tract. The vasculitis produced by this disease includes the formation of fibrous, scarring nodules called granulomas. Symptoms include nose bleeds, ear infections, cough, shortness of breath, and chest pain. There may be bleeding in the lungs, and a patient may cough up blood. The kidneys, eyes, and skin are also frequently involved.

KEY TERMS

Aneurysm—A weakened area in the wall of a blood vessel which causes an outpouching or bulge. Aneurysms may be fatal if these weak areas burst, resulting in uncontrollable bleeding.

Antibody—Specialized cells of the immune system which can recognize organisms that invade the body (such as bacteria, viruses, and fungi). The antibodies are then able to set off a complex chain of events designed to kill these foreign invaders.

Antigen—A special, identifying marker on the outside of cells.

Autoimmune disorder—A disorder in which the body's antibodies mistake the body's own tissues for foreign invaders. The immune system therefore attacks and causes damage to these tissues.

Immune system—The system of specialized organs, lymph nodes, and blood cells throughout the body which work together to prevent foreign invaders (bacteria, viruses, fungi, etc.) from taking hold and growing.

Inflammation—The body's response to tissue damage. Includes hotness, swelling, redness, and pain in the affected part.

Petechia—A tiny, purplish-red spot on the skin, caused by the leakage of a bit of blood out of a vessel and under the skin.

Purpura—A large, purplish-red circle on the skin, caused by the leakage of blood out of a vessel and under the skin.

Diagnosis

Diagnosis of any type of vasculitis involves demonstrating the presence of a strong inflammatory process. Tests which reveal inflammation throughout the

body include **erythrocyte sedimentation rate**, blood tests which may reveal anemia and increased white blood cells, and tests to demonstrate the presence of immune complexes and/or antibodies circulating in the blood. An x-ray procedure, called **angiography**, involves injecting dye into a major artery, and then taking x-ray pictures to examine the blood vessels, in order to demonstrate the presence of inflammation of the vessel walls. Tissue samples (biopsies) may be taken from affected organs to demonstrate inflammation.

Treatment

Even though there are many different types of vasculitis, with many different symptoms based on the organ system affected, treatments are essentially the same. They all involve trying to decrease the activity of the immune system. Steroid medications (like prednisone) are usually the first types of drugs used. **Steroids** work by interfering with the chemicals involved in the inflammatory process. More potent drugs for severe cases of vasculitis have more serious side effects. These include drugs like cyclophosphamide. Cyclophosphamide works by actually killing cells of the patient's immune system.

Prognosis

The prognosis for vasculitis is quite variable. Some mild forms of vasculitis, such as those brought on by reactions to medications, may resolve totally on their own and not even require treatment. **Temporal arteritis**, **serum sickness**, Henoch-Schonlein purpura, and Kawasaki's disease usually have excellent prognoses, although when Kawasaki's affects the heart, there is a high death rate. Other types of vasculitis were always fatal, prior to the availability of prednisone and cyclophosphamide, and continue to have high rates of fatal complications. These include polyarteritis nodosa and Wegener's granulomatosis.

Prevention

Because so little is known about what causes a particular individual to develop vasculitis, there are no known ways to prevent it.

Vasectomy

Definition

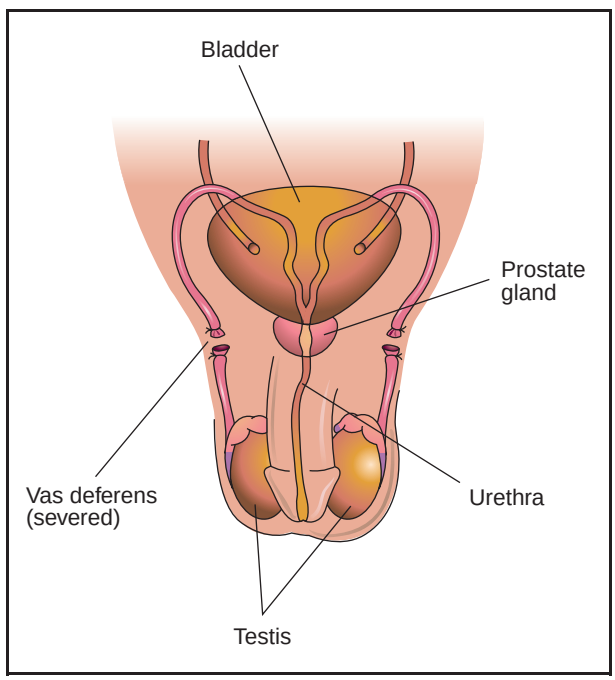
A vasectomy is a surgical procedure performed on adult males in which the vasa deferentia (tubes that carry sperm from the testicles to the seminal vesicles) are cut, tied, cauterized (burned or seared), or otherwise interrupted. The semen no longer contains sperm after the tubes are cut, so conception cannot occur. The testicles continue to produce sperm, but the sperm die and are absorbed by the body.

Purpose

The purpose of the vasectomy is to provide reliable **contraception**. Research indicates that the level of effectiveness is 99.6%. Vasectomy is the most reliable method of contraception and has fewer complications and a faster recovery time than female sterilization methods. Some insurance plans will cover the cost of the procedure.

Demographics

Approximately 500,000 vasectomies are performed annually in the United States. About one out



Vasectomy is a surgical procedure performed on males in which the vas deferens (tubes that conduct sperm from the testicles to the penis) are cut, tied, cauterized, or otherwise interrupted. *(Illustration by Electronic Illustrators Group. © Cengage Learning®.)*

WWW.BOOKBAZ.IR

KEY TERMS

Ejaculation—The act of expelling semen through the penis during orgasm. The fluid that is released is called the ejaculate.

Epididymitis—Inflammation of the small tube that rests on top of the testicle and is part of the system that carries sperm from the testicle to the penis. The condition can be successfully treated with antibiotics, if necessary.

Scrotum—The sac that contains the testicles.

Sperm granuloma—A collection of fluid that leaks from an improperly sealed or tied vas deferens. The fluid usually disappears on its own semen but can be drained, if necessary.

Testicles—The two egg-shaped organs found in the scrotum that produce sperm.

Tubal ligation—A female sterilization surgical procedure in which the fallopian tubes are tied in two places and cut between. This prevents eggs from moving from the ovary to the uterus.

Vas deferens (plural, vasa deferentia)—The Latin name for the duct that carries sperm from the testicle to the epididymis. In a vasectomy, a portion of each vas deferens is removed to prevent the sperm from entering the seminal fluid.

Vasovasostomy—A surgical procedure that is done to reverse a vasectomy by reconnecting the ends of the severed vasa deferentia.

of every six men over the age of 35 has had a vasectomy. Higher vasectomy rates are associated with higher levels of education and income.

Description

Vasectomies are usually performed in the doctor's office or an outpatient clinic using local **anesthesia**. The area around the patient's scrotum (the sac containing the testicles that produce sperm) is shaved and cleaned with an antiseptic solution to reduce the chance of infection. A small incision is made in the scrotum. Each vas deferens (one from each testicle) is tied in two places with nonabsorbent (permanent) sutures and the tube is severed between the ties. The ends may be cauterized (burned or seared) to decrease the chance that they will leak or grow back together.

"No-scalpel" vasectomies are gaining in popularity. Instead of an incision, a small puncture is made into the scrotum. The vasa deferentia are cut and sealed in a manner similar to that described above. No stitches are necessary and the patient has less **pain**. Other advantages include less damage to the tissues, less bleeding, less risk of infection, and less discomfort after the procedure. The no-scalpel method was developed in China in the mid-1970s and has been used in the United States since 1988. About one-third of vasectomies in the United States are performed with this technique.

The patient is not sterile immediately following the procedure. Men must use other methods of contraception until two consecutive semen analyses confirm that there are no sperm present in the ejaculate. It takes about four to six weeks, or 15–20 ejaculations, to clear all of the sperm from the tubes.

In some cases, vasectomies may be reversed by a procedure known as a vasovasostomy. In this procedure, the surgeon reconnects the ends of the severed vasa deferentia. A vasectomy should be considered permanent, however, as there is no guarantee of successful reversal. Vasovasostomies are successful in approximately 40%–50% of men, although the success rate varies considerably with the individual surgeon. In the mid 2000s between 6% and 12% of American men were requesting reversals of their vasectomies. The cost of the procedure in the United States can be considerable, ranging from $5,000–20,000.

Preparation

No special physical preparation is required for a vasectomy. The physician will first assess the patient's general health in order to identify any potential problems that could occur. The doctor will then explain the possible risks and side effects of the procedure. The patient is asked to sign a consent form that indicates that he understands the information he has received and gives the doctor permission to perform the operation.

Aftercare

Following the surgery, ice packs are often applied to the scrotum to decrease pain and swelling. A dressing (or athletic supporter) that supports the scrotum can also reduce pain. Mild over-the-counter (OTC) pain medication such as **aspirin** or **acetaminophen** (Tylenol) should be able to control any discomfort. Activities may be restricted for one or two days, and no sexual intercourse for three or four days.

Risks

There are very few risks associated with vasectomy other than infection, bruising, **epididymitis** (inflammation of the tube that carries the sperm from the testicle to the penis), and sperm granulomas (collections of fluid that leaks from a poorly sealed or tied vas deferens). These complications are easily treated if they do occur. Patients do not experience difficulty achieving an erection, maintaining an erection, or ejaculating. There is no decrease in the production of the male hormone (testosterone), and the patient's sex drive and sexual performance are not altered. Vasectomy is safer and less expensive than **tubal ligation** (sterilization of a female by cutting the fallopian tubes to prevent conception).

According to both the World Health Organization (WHO) and the National Institutes of Health (NIH), there is no evidence that a vasectomy will increase a man's long-term risk of **testicular cancer**, **prostate cancer**, or **heart disease**.

Results

Vasectomies are more than 99% successful in preventing conception. As such, male sterilization is one of the most effective methods of contraception available.

Morbidity and mortality rates

Complications occur in approximately 5% of vasectomies. The rates of incidence of some of the more common complications include:

- mild bleeding into the scrotum: 1 in 400
- major bleeding into the scrotum: 1 in 1,000
- infection: 1 in 100
- epididymitis: 1 in 100
- sperm granuloma: 1 in 500
- persistent pain: 1 in 1,000

Fournier **gangrene** is a very rare but possible complication of vasectomy in which the lining of tissue underneath the skin of the scrotum becomes infected (a condition called fasciitis). Fournier gangrene progresses very rapidly and is treated with aggressive antibiotic therapy and surgery to remove necrotic (dead) tissue. Despite treatment, a mortality rate of 45% has been reported for this condition.

Alternatives

There are numerous options available to couples who are interested in preventing **pregnancy**. The most common methods are female sterilization, **oral contraceptives**, and the male condom. Female sterilization has a success rate of 99.5%; oral contraceptives, 95–99.5%; and the male condom, 86%–97%.

Vasodilators

Definition

Vasodilators are medicines that act directly on muscles in blood vessel walls to make blood vessels widen (dilate).

Purpose

Vasodilators are used to treat high blood pressure (**hypertension**). By widening the arteries, these drugs

WWW.BOOKBAZ.IR

allow blood to flow through more easily, reducing blood pressure. Controlling high blood pressure is important because the condition puts a burden on the heart and the arteries, which can lead to permanent damage over time. If untreated, high blood pressure increases the risk of **heart attack**, **heart failure**, **stroke**, or kidney failure. Vasodilators usually are prescribed with other types of blood pressure drugs and rarely are used alone.

Description

Examples of vasodilators are hydralazine (Apresoline) and **minoxidil** (Loniten). The vasodilator hydralazine also may be used to control high blood pressure in pregnant women or to bring down extremely high blood pressure in emergency situations. In the forms used for treating high blood pressure (tablets or injections), these drugs are available only with a physician's prescription. A liquid form of minoxidil, used to promote hair growth in people with certain kinds of baldness and is applied directly to the scalp, and is sold without a prescription.

Recommended dosage

The recommended dosage depends on the type of vasodilator. The physician who prescribed the drug or the pharmacist who filled the prescription can recommend the correct dosage. This medicine should only be used as directed.

Physicians usually prescribe vasodilators along with other blood pressure medicines. Taking each drug at the correct time is extremely important. Healthcare providers can offer suggestions on how to remember when to take each drug.

Precautions

Seeing a physician regularly while taking a vasodilator is important, especially during the first few months. The physician will check to make sure the medicine is working as it should and will watch for unwanted side effects. People who have high blood pressure often feel fine. However, even when they feel well, patients should keep seeing their physicians and taking their medicine.

Vasodilators will not cure high blood pressure, but will help control the condition. To avoid the serious health problems that high blood pressure can cause, patients may have to take medicine for the rest of their lives. Furthermore, medicine alone may not be enough. People with high blood pressure also may need to avoid certain foods and keep their weight under control. The healthcare professional who is treating the condition can offer advice on what measures may be necessary.

Some people feel dizzy or have headaches while using this medicine. These problems are especially likely to occur in older people, who are more sensitive than younger people to the medicine's effects. Individuals who take these drugs should not drive, use machines, or do anything else that might be dangerous until they know how the drugs affect them.

Special conditions

People who have certain medical conditions or who are taking certain other medicines may have problems if they take vasodilators. In the past, patients with severe aortic stenosis could not use vasodilators because they could cause blood pressure to drop too low and result in severe complications. However, in 2003, a report announced that the vasodilator nitroprusside was safe in these patients and rapidly improved their cardiac function. Before patients take vasodilators, they should be sure to let their physician know about any of these conditions:

ALLERGIES. Individuals who have had an unusual reaction to a vasodilator in the past should let their physician know before taking this type of drug again. The physician also should be told about any **allergies** to foods, dyes, preservatives, or other substances.

PREGNANCY. Several problems—from excess hair growth to blood abnormalities—have been reported in babies whose mothers take certain vasodilators during **pregnancy**. In studies of laboratory animals, hydralazine caused **birth defects** in mice and rabbits, but not in rats. The effects of taking vasodilators during pregnancy have not been specifically studied in humans. Women who are pregnant or who may become pregnant should check with their physicians before using this medicine. Women who become pregnant while taking a vasodilator should tell their physicians right away.

BREASTFEEDING. Women who are **breastfeeding** their babies or who plan to breastfeed should check with their physicians before using this medicine.

OTHER MEDICAL CONDITIONS. Using a vasodilator to lower blood pressure may worsen the problems that result from **heart disease**, blood vessel disease, or a recent heart attack or stroke. This medicine also may make **angina** (chest **pain**) worse. Vasodilators may make pheochromocytomas (tumors of the adrenal medulla), more active. Before using a vasodilator,

KEY TERMS

Adrenal gland—One of a pair of organs located next to the kidneys. The adrenal glands produce hormones that control many body functions.

Adrenal medulla—The inner part of the adrenal gland. The adrenal medulla produces the hormones epinephrine (adrenaline), which stimulates the heart, tightens blood vessels, and relaxes some smooth muscles, and norepinephrine, which has similar effects.

Arteries—Blood vessels that carry blood away from the heart to the cells, tissues, and organs of the body.

people with any of these medical problems should make sure their physicians are aware of their conditions.

People with **kidney disease** also should check with their physicians before using a vasodilator. Side effects may be greater in these people because their kidneys are slow to clear the medicine from the body.

USE OF CERTAIN MEDICINES. Taking vasodilators with certain other drugs may affect the way the drugs work or may increase the chance of side effects. Any other prescription or nonprescription (over-the-counter) medicine should not be taken along with a vasodilator unless it has been discussed with the physician who prescribed the vasodilator.

Side effects

Some side effects of vasodilators go away as the body adjusts to the drug and do not need medical attention unless they continue or interfere with normal activities. These include:

- headache
- nausea or vomiting
- diarrhea
- loss of appetite

In addition, minoxidil may cause a temporary increase in hair growth, especially on the face, arms, and back. Patients who are bothered by this should check with their physicians.

Other side effects of vasodilators should have medical attention. Rapid or irregular heartbeat are reasons to check with a physician immediately. If any of the following problems occur, a physician should be consulted as soon as possible:

- chest pain
- muscle pain
- joint pain
- pain, numbness, tingling, or weakness in the hands or feet
- swollen feet or lower legs
- swollen lymph nodes
- bloating
- fever and sore throat
- general discomfort or feeling of illness
- weakness
- blisters on skin; skin rash or itching; flushing or redness of the skin

Additional side effects are possible. Individuals who have unusual symptoms while taking a vasodilator should get in touch with their physician.

Interactions

Vasodilators may interact with other medicines. When this happens, the effects of one or both of the drugs may change or the chance of side effects may be greater. In addition, many prescription and nonprescription (over-the-counter) drugs may affect blood pressure. *No other medication should be taken without the approval of the physician who prescribed the vasodilator*. In particular, avoiding over-the-counter medicines for appetite control, colds, **cough**, sinus problems, **asthma**, hay **fever**, and other allergies, should be avoided as these may increase blood pressure. At the other extreme, dangerously low blood pressure may result when drugs such as the blood pressure medicine guanethidine (Ismelin) or nitrates, used to treat chest pain, are combined with vasodilators.

Vegetarianism

Definition

Vegetarianism refers to the practice of excluding meat, poultry, and fish from the diet. The word was coined in 1847, when the Vegetarian Society of the United Kingdom—the oldest organized vegetarian group in the world—was founded in Ramsgate, Kent. The society, which has included George Bernard Shaw and Mahatma Gandhi among its members, chose the word *vegetarian* for its name because it is derived from the Latin *vegetus*, which means "lively" or "vigorous," and because it suggests the English word *vegetable*. Vegetarianism is better understood as a lifestyle rather than a diet in the strict sense, as there are many specific plant-based **diets** that could be called vegetarian.

There are several distinctive subgroups of vegetarians:

- Vegans: Sometimes called strict vegetarians, vegans are people who exclude all animal products from their diet or clothing, whether or not they involve the death of an animal. Vegans will not use honey or dairy products, for example, and will not wear clothing made of wool, silk, fur, or leather, or use bedding stuffed with down.
- Ovolactovegetarians: Vegetarians in this category will use eggs, milk, and other dairy products on the grounds that these foods are not obtained by killing animals.
- Ovovegetarians: Vegetarians who include eggs in the diet but not milk or milk products.
- Lactovegetarians: Vegetarians who use milk and milk products but not eggs.
- Semivegetarians or pesce/pollo vegetarians: People who include fish or chicken in the diet but also seek to minimize their consumption of animal protein.
- Fruitarians: Vegetarians who eat only fruits, nuts, seeds, and other plant matter that can be harvested without harming the plant.
- Flexitarians: People who prefer a vegetarian diet but are willing to eat meat, fish, or chicken on exceptional occasions.
- Freegans: Anti-consumerist vegans who seek to avoid participating in any practices they regard as exploitative of other people or the environment, in addition to excluding meat and animal products from their diet. Freegans obtain their food by growing it themselves, by barter, or by foraging in refuse bins and restaurant trash receptacles for discarded food. This practice is called "dumpster diving" in the United States and "skipping" in the United Kingdom.

(Table by PreMediaGlobal. © 2013 Cengage Learning.)

Origins

Vegetarianism is a lifestyle that has emerged in various civilizations around the world at different points in history out of different sets of motives, which will be described in the historical order of their appearance. Archaeological findings indicate that prehistoric humans were not vegetarians but obtained about a third of their daily calories from meat or other animal products. The structure of the human digestive tract suggests that humans evolved as omnivores (animals that feed on both plant and animal substances), as human intestines are relatively short in comparison with the lengthy intestines found in herbivores (plant-eating animals). Like the stomachs of other carnivores (meat-eating animals) and omnivores, the human stomach secretes pepsin, an enzyme necessary for digesting the proteins found in meat rather than plant matter. The human mouth contains pointed teeth (canines and incisors) adapted for tearing meat as well as teeth with flat crowns (molars) for chewing plant matter. In addition to the anatomical evidence, anthropologists have not discovered any primitive societies in the past or present whose members maintained good health and consumed a purely vegetarian diet. All contemporary indigenous groups that are healthy include fish or dairy products in their diet, and most eat meat, even if only in small amounts or on rare occasions.

Religious vegetarianism

Religious belief is the oldest historical motive for vegetarianism. Hinduism is the earliest of the world's major religions known to have encouraged a vegetarian

DR. JOHN HARVEY KELLOGG (1852–1943)

John Harvey Kellogg. *(AP Images.)*

John Harvey Kellogg is known as the father of modern breakfast cereal. He was born in Tyrone Township, Michigan, on February 26, 1852, into a Seventh Day Adventist family. At age 12, he became an apprentice at the Review and Herald Press, a publishing company run by the church. He attended school in Battle Creek, Michigan. He attended Bellevue Hospital Medical College in New York where he received his medical degree in 1875. In 1876, at the age of 24, Kellogg became an abdominal surgeon and superintendent of the Western Health Reform Institute, which he renamed the Battle Creek Sanitarium. There, he began applying his theories about natural living to his medical practice. A vegetarian himself, he first advocated a diet high in whole grains, fruits, nuts, and legumes. He later included all types of vegetables in the diet. His controversial health regimen included morning calisthenics, open-air sleeping, cleansing enemas, chewing food hundreds of times before swallowing, and drinking plenty of water.

In the 1890s, Kellogg established a laboratory at the sanitarium to develop more nutritious foods. His brother, Will Keith Kellogg, joined in his research. In 1895 they developed a breakfast cereal of wheat flakes called Granose. The cereal quickly grew in popularity and was soon sold by mail order. This was followed by rice flakes and corn flakes. The brothers established the Sanitas Food Company. But philosophical differences led them to split into two companies. Will founded the W. K. Kellogg Company, which retained the rights to the cereal products. John set up the Battle Creek Food Company, which produced coffee substitutes and soymilk. John Kellogg also edited *Good Health Magazine*, which promoted vegetarianism, for 60 years. In 1904, he published a book, *The Miricle of Life*. He continued to promote his version of healthy living and radical techniques until his death in 1943.

lifestyle. As of 2014, Hinduism accounts for more of the world's practicing vegetarians—70%—than any other faith or political conviction. Different Hindus, however, explain their commitment to vegetarianism in different ways. Some associate vegetarianism with the doctrine of *ahimsa*, or nonviolence, which forbids the shedding of animal as well as human blood. Others believe that animals have souls and that those who kill them will acquire bad karma and suffer in their next reincarnation. Last, some Hindus believe that their gods will not accept nonvegetarian offerings.

The Jain religion, an ascetic offshoot of Hinduism that began in the sixth century BC, requires followers to adopt a vegan diet; they may also not eat roots because to do so kills the plant. Most Jains fast on holy days and at other times throughout the year, as they believe that **fasting** strengthens self-control and protects the believer from accumulating bad karma.

In ancient Greece, the followers of the philosopher and mathematician Pythagoras (c. 582–507 BC) practiced an ascetic lifestyle, following a vegetarian diet and abstaining from animal bloodshed, including sacrifices to the Greek gods. Neoplatonist philosophers of the third and fourth centuries AD revived the Pythagorean notion that vegetarianism helps to purify the soul. As a result of the association of a plant-based diet with Pythagoras, European Christians in the sixteenth and seventeenth centuries who practiced vegetarianism were often called Pythagoreans.

Mainstream Christianity in both its Eastern and Western forms has never made year-round vegetarianism mandatory for laypeople; however, there is a long tradition of monastic vegetarianism going back at least as far as the Desert Fathers in the third and fourth centuries AD. In addition, many Christians abstain from meat during certain seasons of the church year (Lent and Advent). One reason for vegetarian diets in some of the monastic orders is the belief that eating meat increases temptations to anger and violence. Another reason, found more commonly among evangelical Protestants, is the interpretation of Genesis 1:29 and other Bible passages as meaning

WWW.BOOKBAZ.IR

that God originally intended humans to be vegetarians and that God wants his present-day followers to be responsible stewards of the earth. The Christian Vegetarian Association (CVA), which welcomes Roman Catholics as well as mainstream and evangelical Protestants, was founded in 1999.

One Christian denomination that was formed in the United States in the nineteenth century, namely the Seventh-day Adventist Church, has expected its members to be vegetarians since its beginning. Members of the church have been studied by the National Institutes of Health (NIH) and the National Cancer Institute (NCI) since 1960. NIH findings indicate that Adventist men live on average seven years longer than men in the general population, and Adventist women eight years longer than their non-Adventist counterparts.

Many members of New Age groups, as well as some atheists and agnostics, practice vegetarian or vegan lifestyles out of respect for nature or for the earth, even though they would not consider themselves religious in the conventional sense.

Environmental vegetarianism

The application of scientific methods to agriculture in the eighteenth and nineteenth centuries also allowed people to calculate for the first time the cost to the environment of raising animals for meat. As early as the 1770s, the English clergyman William Paley had urged a vegetarian lifestyle on the grounds that an acre of land used to raise fruits and vegetables could support twice the number of people as an acre used to graze animals. A common ethical argument for vegetarianism in the early twenty-first century is that 40% of the world's grain goes to feed animals raised for meat rather than to feed people and that world hunger could be eliminated if even half this grain could be redistributed to undernourished populations. According to the North American Vegetarian Society (NAVS), 15 vegans can be fed on the same amount of land needed to feed one person consuming a meat-based diet.

Animal rights vegetarianism

Commitment to a vegetarian diet as a way to reduce the suffering of animals—sometimes called compassion-based vegetarianism—emerged during the mid-nineteenth century, a period that also witnessed the foundation of the first groups devoted to animal welfare. The Royal Society for the Prevention of Cruelty to Animals (RSPCA) was given its charter by Queen Victoria in 1840, seven years before the organization of the Vegetarian Society. The American Society for the Prevention of Cruelty to Animals (ASPCA) was founded in New York City by Henry Bergh in 1866. In addition to ongoing concern about maltreatment of household pets and working animals, the advent of factory farming has intensified the revulsion many people feel regarding the use of animals for human dietary consumption and clothing.

Description

The 2003 vegetarian food guide

Vegetarianism entered the medical mainstream in 2003 when the Academy of **Nutrition** and Dietetics (formerly the American Dietetic Association [ADA]) and the Dietitians of Canada (DC) jointly issued "A New Food Guide for North American Vegetarians." This document contained the first major revisions of the familiar U.S. Department of Agriculture (USDA) food guide pyramid and Canada's Food Guide to Healthy Eating (CFGHE) intended for vegetarians. While the USDA and Canadian food guides were the first to consider overnutrition as a serious health problem and while they emphasized the importance of plant foods in the diet, they did not include guidelines for planning vegetarian diets. The 2003 food guide borrowed the general concept of food groups from the older guides, but reclassified foods into five plant-based groups:

- Grains: The foundation of the vegetarian diet. Whole grains are best, but enriched refined grains are also acceptable.
- Vegetables and fruits: The ADA and DC recommend that vegetarians choose both vegetables and fruits rather than using only one or the other.
- Legumes, nuts, and other protein-rich foods: Legumes include soymilk and tofu. Dairy products used by ovo- and lactovegetarians also fall into this category, as do meat substitutes.
- Fats: Vegetarians who do not eat fish require plant-based sources of omega-3 fats.
- Calcium-rich foods: Adult vegetarians require eight servings from this category each day. Each serving, however, counts toward one of the other food choices, as calcium-rich foods can be found across the other food groups.

The minimum number of servings per food group in this diet would provide about 1,400 or 1,500 calories per day. Nonsedentary adults can meet higher energy needs by choosing more servings from any of the basic five groups. Sweets and alcohol should be used only sparingly.

Dietary supplements are recommended for vegetarians over 50 and for vegans, based on studies conducted by the Institute of Medicine (IOM).

Some specific vegetarian diets

Vegetarian diets can accommodate a wide variety of regional and ethnic cuisines as well as different philosophical or religious approaches. The following are only a few of the possible choices:

MEDITERRANEAN DIET. In its origin, the **Mediterranean diet** was not a purely vegetarian diet. It is, however, sparing in its use of red meat and eggs, and low in its use of fish and poultry. It can thus be easily adapted to a vegetarian or pesce/pollo vegetarian diet. The Mediterranean diet is high in its use of whole grains, fruits, nuts, and high-fiber vegetables; it appeals to many people because of its wide choice of flavorful foods.

MACROBIOTIC DIET. The macrobiotic diet, which was brought to Europe and North America from Japan in the 1960s, is associated with the Eastern concepts of yin and yang as well as with the elimination of animal products from the diet. This diet also involves such changes in eating habits as chewing each mouthful of food at least 50 times, drinking liquids only when thirsty, avoiding the use of aluminum cookware, and cooking foods on a wood stove rather than using electrical appliances.

ORNISH DIET. Developed by a medical doctor to reverse the signs of **heart disease**, the Ornish diet has also been popularized as a weight-loss program. It is a strict low-fat, high-fiber diet that excludes red meat, poultry, and fish, although people following this diet may use limited amounts of egg whites, fat-free milk, and other fat-free dairy products.

SEVENTH-DAY ADVENTIST DIET. Seventh-day Adventists (SDAs) have followed vegetarian dietary regimens since the denomination was first organized in 1863. The diet recommended by the church's General Conference Nutrition Council (GCNC) in the early 2000s is an ovolactovegetarian diet high in whole-grain breads and pastas and fresh vegetables and fruits, with moderate use of nuts, seeds, and low-fat dairy products and limited use of eggs. Some SDAs prefer a vegan diet. The church has its own professional organization for dietitians, which is affiliated with the ADA, and encourages all its members to follow the ADA guidelines for vegetarians.

Tips for starting a vegetarian diet

The ADA offers the following suggestions for people considering vegetarianism:

- Make a list of meatless dishes. Pizza, chili, vegetable soups, salads, bean casseroles, Oriental stir-fried vegetables, and pasta dishes are common favorites.
- Look through some vegetarian cookbooks and copy the recipes that seem appealing.
- Check out natural food stores and try some of their products.
- Visit ethnic restaurants—Chinese, Japanese, Thai, Indian, Vietnamese, or Middle Eastern, for example—and sample some of their meatless dishes.
- Try meat substitutes (sometimes called meat analogues or "mock meat") made from textured vegetable protein (TVP) or tofu (bean curd). Veggie burgers, veggie hot dogs, and imitation sausage are popular items of this type.

Function

Vegetarian diets are adopted by people in developed countries primarily for ethical or religious reasons rather than economic necessity—although some dietitians do point out that plant-based foods are usually easier on the household food budget than meat. Another more recent reason is the growing perception that plant-based diets are a form of preventive health care for people at increased risk of such diseases as heart disease, type 2 diabetes, and some forms of cancer. Adolescents, however, are more likely to adopt vegetarian diets as a weight-reduction regimen.

Benefits

The long-term NIH study of Seventh-day Adventists began to report in the 1970s and 1980s that lowered blood pressure, lower rates of cardiovascular disease and **stroke**, lower blood **cholesterol** levels, and lowered risks of colon and **prostate cancer** were associated with a vegetarian diet. In particular, SDAs were only half as likely to develop type 2 (adult-onset) diabetes as were nonvegetarian Caucasians. Although it is possible to gain weight on a vegetarian diet, most people lose weight, especially in the first few months, and most vegetarians have lower body mass indices (an important diagnostic criterion of **obesity**) than their meat-eating counterparts.

Several studies carried out in Germany and Austria reported in 2006 that vegetarian diets appear to be effective in lowering the risk of **rheumatoid arthritis**, **osteoporosis**, **kidney disease**, **gallstones**, **diverticulitis**, and **dementia** as well as heart attacks, stroke, and diabetes.

In addition to lowering the risk of chronic degenerative diseases, vegetarian diets have also been shown

WWW.BOOKBAZ.IR

to be useful in treating **constipation** in adults and children, and **dysmenorrhea** (painful menstrual periods) in women of childbearing age.

Precautions

The ADA strongly recommends that people consult a registered dietitian as well as their primary physician before starting a vegetarian diet. The reason for this precaution is the variety of vegetarian regimens as well as the variations in height, weight, age, genetic inheritance, food preferences, level of activity, geographic location, and preexisting health problems among people. A nutritionist can also help design a diet that a new vegetarian will enjoy eating as well as ensure that he or she is getting adequate nourishment and other health benefits.

Risks

The longstanding concern about vegetarian diets is the risk of nutritional deficiencies, particularly for such important nutrients as protein, **minerals** (iron, **calcium**, and zinc), **vitamins** (**vitamin D**, riboflavin, vitamin B_{12}, and **vitamin A**), iodine, and **omega-3 fatty acids**. The 2003 vegetarian food guide recommends that vegetarians over 50 years of age as well as vegans in all age groups take supplements of vitamin B_{12} and vitamin D, or use foods fortified with these nutrients. Vitamin D supplements are particularly important for vegans living in northern latitudes or other situations in which they receive little sun exposure.

In addition to nutritional concerns, there is some evidence that vegetarian diets may actually increase the risk of **breast cancer** in women, particularly in those who use large amounts of soy-based products. Soybeans contain phytoestrogens, or plant estrogens, which have been implicated in breast cancer. The plant estrogens in soy-based products may also explain why vegetarians have a disproportionate number of female babies and why these girls have a higher rate of **precocious puberty** than girls born to nonvegetarian mothers.

Research and general acceptance

General acceptance

Vegetarianism is accepted by all mainstream medical associations and professional societies, and is positively recommended by some. The position statement jointly adopted by the ADA and DC in 2003 states: "It is the position of the American Dietetic Association and Dietitians of Canada that appropriately planned vegetarian diets are healthful, nutritionally adequate and provide health benefits in the prevention and treatment of certain diseases. . . . Well-planned vegan and other types of vegetarian diets are appropriate for all stages of the life cycle, including during **pregnancy**, **lactation**, infancy, childhood and adolescence."

The ADA has a professional subgroup called the Vegetarian Nutrition Dietary Practice Group, or DPG, which publishes a quarterly newsletter called *Vegetarian Nutrition Update*, available to nonmembers of the ADA for an annual subscription fee. The Vegetarian Nutrition DPG also has its own website at http://www.vegetariannutrition.net, with articles available to the public on vegetarian diets and cancer prevention, treatment of rheumatoid arthritis, sports nutrition, pregnancy, and vegan diets for children.

Once considered an eccentricity, vegetarianism is widely accepted by the general public in developed countries as a legitimate dietary option. The ADA and DC state that about 2.5% of adults (defined as people over 18 years of age) in the United States and 4% of Canadian adults follow vegetarian diets. The Vegetarian Resource Group (VRG), a nonprofit research organization, conducted a poll in 2006 and estimated that 2.3% of adults in the United States—4.7 million people—were vegetarians, with a third to a half of this group being vegans. In addition, the VRG noted that 30% to 40% of American adults choose vegetarian dishes over meat dishes at least some of the time. Other interesting details from the 2006 poll include:

- People between 45 and 54 years of age were almost twice as likely to be vegetarians as people between 18 and 24 years of age.
- The Northeast had the highest percentage of vegetarians in the general population, with the South having the lowest.
- People who graduated from college were twice as likely to be vegetarians as those who did not complete high school.
- Hispanics were more likely to be vegetarians than either Caucasians or African Americans.
- There was no correlation between household income and a vegetarian lifestyle; people at all income levels seemed to be equally likely to become vegetarians.

Most opposition to vegetarianism in developed countries is interpersonal rather than scientific or political, as some vegetarians are perceived as developing a sense of moral or spiritual superiority to nonvegetarians and may make themselves socially unpopular by criticizing or lecturing others for continuing to eat meat. NAVS advises new vegetarians, "Be cheerful about your choices [but] remember to let people come to their own dietary conclusions."

KEY TERMS

Carnivore—An animal whose diet consists mostly or entirely of meat. Cats, wolves, snakes, birds of prey, frogs, sharks, spiders, seals, and penguins are all carnivores.

Dietitian—A healthcare professional who specializes in individual or group nutritional planning, public education in nutrition, or research in food science. To be licensed as a registered dietitian (RD) in the United States, a person must complete a bachelor's degree in a nutrition-related field and pass a state licensing examination. Dietitians are sometimes called nutritionists.

Factory farming—A term that refers to the application of techniques of mass production borrowed from industry to the raising of livestock, poultry, fish, and crops. It is also known as industrial agriculture.

Freegan—A vegan who obtains food outside the mainstream economic system, most often by growing it, bartering for it, or scavenging for it in restaurant or supermarket trash bins.

Fruitarian—A vegetarian who eats only plant-based products, such as fruits, seeds, and nuts, that can be obtained without killing the plant.

Herbivore—An animal whose diet consists primarily or entirely of plant matter. Herbivorous animals include deer, sheep, cows, horses, elephants, giraffes, and bison.

Lactovegetarian—A vegetarian who consumes milk and cheese in addition to plant-based foods.

Obligate carnivore—An animal that must have meat in its diet to maintain health. Cats are obligate carnivores, although humans and most breeds of dogs are not.

Omnivore—An animal whose teeth and digestive tract are adapted to consume either plant or animal matter. The term does not mean, however, that a given species consumes equal amounts of plant and animal products. Omnivores include bears, squirrels, opossums, rats, pigs, foxes, chickens, crows, monkeys, most dogs, and humans.

Ovolactovegetarian—A vegetarian who consumes eggs and dairy products as well as plant-based foods. The official diet recommended to Seventh-day Adventists is ovolactovegetarian.

Ovovegetarian—A vegetarian who eats eggs in addition to plant-based foods.

Pepsin—A protease enzyme in the gastric juices of carnivorous and omnivorous animals that breaks down the proteins found in meat. Its existence in humans is considered evidence that humans evolved as omnivores.

Pesce/pollo vegetarian—A term used to describe semivegetarians; that is, people who avoid consuming red meat but will include fish (*pesce* in Italian) or chicken (*pollo* in Italian) in their diet. Other terms for semivegetarians include *piscitarian* or *fishetarian* for those who eat only fish but not chicken, and *pollo-vegetarian* or *pollotarian* for those who add chicken but not fish to their vegetarian diet.

Textured vegetable protein (TVP)—A meat substitute made from defatted soybean flour formed into a dough and cooked by steam while being forced through an extruder. It resembles ground beef in texture and can replace it in most recipes. TVP is also known as textured soy protein or TSP.

Tofu—Bean curd; a soft food made by coagulating soymilk with an enzyme, calcium sulfate, or an organic acid, and pressing the resulting curds into blocks or chunks. Tofu is frequently used in vegetarian dishes as a meat or cheese substitute.

Vegan—A vegetarian who excludes all animal products from the diet, including those that can be obtained without killing the animal. Vegans are also known as strict vegetarians.

Research

As has been noted in Europe as well as the United States, the emphasis in medical research on vegetarian diets has shifted from concern about nutritional deficiencies in people following these diets to the role of vegetarianism in preventing or treating chronic diseases. It was the NIH's studies of Seventh-day Adventists that first indicated that vegetarian diets can lower the risk of heart disease, stroke, and type 2 diabetes. The Adventist Health Study received new funding in 2003 for its continuation. The NIH regularly conducts clinical trials to evaluate the advantages of vegetarian diets in managing certain conditions; current trials are available online at http://clinicaltrials.gov.

One area of concern, however, is in veterinary medicine—namely, the trend among some pet owners to put dogs and cats on vegetarian diets, often with homemade foods. Cats in particular are at risk of

WWW.BOOKBAZ.IR

malnutrition and eventual blindness on a vegetarian or vegan diet because they are obligate carnivores (must have meat in the diet). Their bodies cannot form taurine (an amino acid), thiamin, retinol (a form of vitamin A essential to healthy eye tissue), and vitamin B_{12}—all micronutrients found primarily in meat. The Vegetarian Society (UK) has an information sheet warning against putting cats on a vegetarian diet, while the American Veterinary Medical Association (AVMA) strongly urges vegetarian pet owners to consult their veterinarian before offering either dogs or cats vegetarian pet food.

Rebecca J. Frey, PhD

Vegetative state

Definition

A coma-like state characterized by open eyes and the appearance of wakefulness is defined as vegetative.

Description

The vegetative state is a chronic or long-term condition. This condition differs from a persistent vegetative state (PVS, a state of **coma** that lacks both awareness and wakefulness) since patients have awakened from coma, but still have not regained awareness. In the vegetative state patients can open their eyelids occasionally and demonstrate sleep-wake cycles. They also completely lack cognitive function. The vegetative state is also called coma vigil.

Causes and symptoms

The vegetative state can be caused by:

- cardiac arrest

- prolonged and profound hypoglycemia (an abnormal and severe decrease in blood sugar)
- carbon monoxide poisoning
- head injury
- brain hemorrhage
- compression of the brainstem
- tumors
- bilateral hemispheric demyelination (a loss of nerve cells)
- injury of the brain following infections (meningitis or encephalitis)
- neurodegenerative diseases
- anencephaly (an abnormality of the brain and skull)
- diffuse nerve cell injury

Patients in a vegetative state apparently have functioning of a special area in the brain called the reticular activating system (RAS) responsible for sleep-wake cycles. The connections that integrate more complex abilities such as awareness are interrupted. Patients in the vegetative state can open and close eyes spontaneously. They may appear to track or follow objects with their eyes. Patients may chew and swallow food placed in the mouth. The vegetative patient does not respond to sound, hunger, or **pain**. Patients cannot obey verbal commands and lack local motor responses. Additionally, these patients cannot talk in comprehendible terms and they may become noisy, restless, and hypermobile. These patients are in a state of arousal but completely lack awareness.

Diagnosis

Diagnosis of vegetative state depends on the primary cause of brain dysfunction. A comprehensive history and neurological examination, neuroimaging studies, and chemical analysis of the blood are essential. Additionally, special tests such as cerebrospinal fluid (CSF, the fluid that bathes and nourishes the brain and spinal cord) analysis and **electroencephalography** (EEG analyzes the electrical activity within the brain) may be indicated to establish a diagnosis.

Treatment

Treatment is directed to presenting symptoms and patient needs. Patients require constant monitoring and assistance with feeding, hydration hygiene, assisted movement (to help prevent **ulcers** and **blood clots** in the legs), and elimination of waste products.

KEY TERMS

Cognitive—The ability (or lack of) to think, learn, and memorize.

Hypermobility—Increased movement of joints.

Alternatives

There is no known alternative treatment for vegetative patients.

Prognosis

The prognosis is generally poor and the condition can persist chronically.

Prevention

There is no known prevention since this state can occur as a result of unavoidable situations such as an accident, tumor, and bleeding or genetic abnormality.

Velopharyngeal insufficiency

Definition

Velopharyngeal insufficiency is the improper closing of the velopharyngeal sphincter (soft palate muscle) during speech characterized by an acute nasal quality of the voice.

Description

At the back of the mouth is a circle of structures that include the tonsils, the tongue, and the palate. During speech, this apparatus must close off the nose for proper articulation of the explosive consonants "p," "b," "g," "t," and "d." If it does not close, there is a snort sound produced through the nose. Improper

WWW.BOOKBAZ.IR

KEY TERMS

Adenoids—Lymph glands just above the tonsils and the palate.

Cleft palate—Congenital defect marked by a split in the roof of the mouth.

Nasopharyngoscopy—A diagnostic procedure that examines the nasal passageways and pharynx with an instrument outfitted with an optical system.

Pharynx—A canal located between the mouth cavity and the esophagus.

Tonsillectomy—Surgical removal of the tonsils.

Tonsils—Lymph glands in the throat, just behind the back teeth.

function of this structure also produces a nasal tone to the voice.

Causes and symptoms

There are three main causes for this defect:

- Cleft palate is a congenital condition, producing a defect in the palate that allows air to escape upward during speech.
- If tonsil and adenoid surgery is done improperly, velopharyngeal insufficiency may result. The occurrence rate is approximately one in every 2,000–3,000 tonsillectomies.
- Nerve or muscle disease may paralyze the muscles that operate the velopharyngeal sphincter.

The primary symptom is the speech impediment. Some people develop a change in their speaking pattern or a series of facial grimaces to try to overcome the difficulty. If the condition is acute, regurgitation through the nose may occur.

Diagnosis

Examination of the velopharyngeal sphincter through **ultrasound** scans, fiber-optic nasopharyngoscopy, and videofluoroscopy will reveal the extent of velopharyngeal insufficiency. Speech and velopharyngeal sphincter movement are compared to make the diagnosis.

Treatment

Velopharyngeal insufficiency is treated with a combination of surgery and **speech therapy**. There are several surgical procedures that can be performed to correct the physical malfunction. They include:

- Pharyngeal flap procedure that moves the skin flap from the pharynx to the soft palate
- Palatal push-back that separates the hard and soft palate in order to lengthen the soft palate
- Pharyngoplasty that lengthens the soft palate by turning the pharyngeal skin flaps
- Augmentation pharyngoplasty that inserts an implant into the pharyngeal wall to enlarge it, thus narrowing the velopharyngeal opening
- Velopharyngeal sphincter reconstruction

Prognosis

The combination of surgery to correct the insufficiency and speech therapy to retrain the voice successfully alleviate velopharyngeal insufficiency.

Vena cava filter

Definition

A vena cava filter is a device inserted into a major vein to prevent a blood clot from entering the lungs.

Purpose

The purpose of a vena cava filter is to prevent a blood clot from potentially traveling to the lungs. A thrombus clot traveling to the lungs is called a **pulmonary embolism** (PE). A thrombus in the deep venous system (the part of the circulation that brings blood back to the heart) represents a disorder of normal hemostasis (the normal clotting of blood).

Insertion of a vena cava filter is indicated for patients who:

- cannot receive medications that can dissolve the clot (anticoagulation therapy)
- have a thrombus in a deeply situated vein
- experiance complication of anticoagulation therapy such as bleeding

KEY TERMS

Embolus—A blood clot that has detached from its site of origin and travels to the lungs (pulmonary artery), where it can rupture the artery, causing death. The plural is emboli.

Pulmonary embolism—A traveling thrombus that has lodged in the pulmonary artery.

Thrombus—A blood clot that can form in a deeply situated vein. The plural is thrombi.

- experiance failure of anticoagulation therapy to prevent pulmonary embolism
- have an embolus in the lungs (pulmonary embolectomy) removed
- have a recurrent embolism while receiving adequate medications
- have significant bleeding complications during anticoagulation

Precautions

There are no significant precautions concerning insertion of a vena cava filter. The devices are usually effective and short-term complications are unusual.

Description

Vena cava filters are usually inserted in to prevent PE caused by a thrombosis in a deep vein (DVT). Approximately 60% of patients who die in a hospital have evidence of PE during **autopsy**. The incidence (number of new cases) of DVT is highest for patients undergoing surgical repair of a fractured hip. However, DVT is common in both surgical and medical patients. DVT is found in 29–33% of patients in medical intensive care units (MICU) and in 27–40% of patients with a **heart attack** (myocardial infarction). Vena cava filters are placed to prevent thrombi from entering the lungs. One new type of filter called the Kim-Ray-Greenfield filter.

Preparation

Insertion of a vena cava filter is an invasive procedure. The patient is prepared for this procedure using standard surgical protocols. The VCF is commonly implanted in the jugular vein in the neck or the femoral vein in the groin. The procedure is generally well tolerated.

Aftercare

This depends on the patient's health status and recommendations for continued care.

Risks

Many patients have died from PE even with a vena cava implantation. Use of a VCF is primarily indicated if there are contraindications for anticoagulation therapy. VCF can increase a patient's susceptibility for developing recurrent DVT.

Results

The patient progresses well and prevention of large emboli that can cause a PE is successful.

Abnormal results

The desired effect is not accomplished and the patient develops a PE resulting in death.

Venography

Definition

Venography is an x-ray test that provides an image of the leg veins after a contrast dye is injected into a vein in the patient's foot.

Purpose

Venography is primarily performed to diagnose **deep vein thrombosis** (a condition that can lead to **pulmonary embolism**). It is the standard procedure used to detect this type of disorder. Venography also can be used to distinguish **blood clots** from obstructions in the veins, to evaluate congenital vein problems, to see how the deep leg vein valves are working, and to identify a vein for arterial bypass grafting.

Precautions

Venography usually is not performed in patients with kidney (renal) problems.

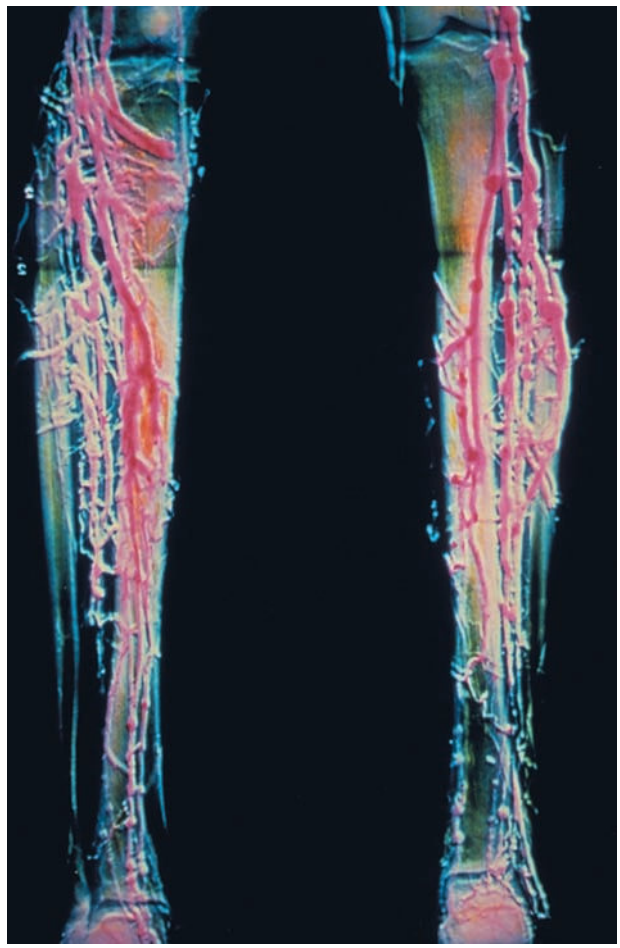
Description

Venography (also called phlebography, ascending contrast phlebography, or contrast venography) is an invasive diagnostic test that provides a constant image of leg veins on a fluoroscope screen. Venography identifies the location, extent, and degree of attachment of the blood clots and enables the condition of the deep leg veins to be assessed. It is especially useful when there is a strong suspicion of deep vein thrombosis but non-invasive tests have failed to identify the disease.

Venography is the most accurate test for detecting deep vein thrombosis. It is nearly 100% sensitive and specific in making this diagnosis (pulmonary **embolism** is diagnosed in other ways). Accuracy is crucial since deep vein thrombosis can lead to pulmonary embolism, a condition that can be fatal.

Venography is not used often, however, because it is painful, expensive, exposes the patient to a fairly high dose of radiation, and can cause complications. In about 5% of cases, there are technical problems in conducting the test. In addition, the test is less accurate in diagnosing problems below the knee. Venography takes between 30–45 minutes and can be done in a physician's office, outpatient center, or a hospital.

In 2003, a report said that computed tomography (CT) scanning could be used to diagnose pulmonary embolism and deep veinous thrombosis in one examination. By combining CT **angiography** and CT venography, researchers could look for both conditions in one procedure with high-speed CT scanners. The procedure was quick and delivered a reduced radiation dose. However, it has not become accepted as a replacement for traditional venography and is only preferred if the patient is clinically stable and requires immediate diagnosis and treatment.



A venographic image of a patient's legs with varicose veins. *(Custom Medical Stock Photo, Inc.)*

During the procedure, the patient lies on a tilting x-ray table. The area where the catheter will be inserted will be shaved, if necessary, and cleaned. Sometimes a local anesthetic is injected to numb the skin at the site of the insertion. A small incision may be required to make a point for insertion. The catheter is inserted and the contrast solution (or dye) is slowly injected. Injection of the dye causes a warm, flushing feeling in the leg that may spread through the body. The contrast solution also may cause slight nausea. About 18% of patients experience discomfort from the contrast solution.

In order to fill the deep venous system with dye, a tight band (or tourniquet) may be tied around the

KEY TERMS

Contrast solution—A liquid dye injected into the body that allows veins to be seen by x rays. Without the dye, the veins could not be seen on x rays.

Deep vein thrombosis—The development or presence of a blood clot in a vein deep within the leg. Deep vein thrombosis can lead to pulmonary embolism.

Invasive—A diagnostic test that invades healthy tissue; in the case of venography, through an incision in a healthy vein.

Pulmonary embolism—An obstruction of a blood vessel in the lungs, usually due to a blood clot, that blocks a pulmonary artery. Pulmonary embolism can be very serious and in some cases is fatal.

ankle of the foot the dye is injected into or the lower extremities may be tilted. The patient is asked to keep the leg still. The doctor also observes the movement of the solution through the vein with a fluoroscope. At the same time, a series of x rays are taken. When the test is finished, fluid is injected to clear the dye from the veins, the catheter is removed, and a bandage is applied over the site of the injection.

Preparation

Fasting or drinking only clear liquids is necessary for four hours before the test. However, sometimes the test is done in an emergency even if the patient has eaten. The contrast solution contains iodine, to which some people are allergic. Patients who have **allergies** or hay **fever**, or have had a bad reaction to a contrast solution, should tell the doctor. A sedative, such as diazepam (Valium), may be prescribed to help the patient relax.

Aftercare

Patients should drink large amounts of fluids to flush the remaining contrast solution from their bodies. The area around the incision will be sore for a few days. If there is swelling, redness, **pain**, or fever, the doctor should be notified. Pain medication may be needed. In most cases, the patient can resume normal activities the next day.

Risks

Venography can cause complications such as phlebitis, tissue damage, and the formation of deep vein thrombosis in a healthy leg. A rare side effect in up to 8% of cases is a severe allergic reaction to the dye. This usually happens within 30 minutes after injection of the dye and requires medical attention.

Results

Normal venography results show proper blood flow through the leg veins.

Abnormal results

Abnormal venography results show well-defined filling defects in veins. Findings include:

- blood clots
- consistent filling defects
- an abrupt end of a test dye column
- major deep veins that are unfilled
- dye flow that is diverted

These results confirm a diagnosis of deep vein thrombosis.

Venous access

Definition

Venous access introduces a needle or catheter into a vein. The venous access can then be used to withdraw blood, administer fluids or blood products, infuse **parenteral nutrition**, and/or administer medications.

Purpose

Venous access is necessary for fluid administration, medication administration, and obtaining blood for chemical analysis. Sites for access include veins located in the peripheral arms or legs, scalp, neck, and bone. Large central veins such as the subclavian vein may also be used to initiate venous access.

Venous access in children may pose special problems since finding appropriate veins and **immobilization** during the procedure may be difficult but essential. For complicated procedures **sedation** may be indicated. Venous access can be performed during

WWW.BOOKBAZ.IR

KEY TERMS

Cannula—Insertion of a tube.

Catheterization—The process of inserting a tubular instrument into a body cavity to permit passage of fluid.

Phlebitis—Inflammation of a vein.

Pneumothorax—The presence of air in the cavity that surrounds the lungs.

emergency situations, and can be performed for outpatients, inpatients, and those who require long term administration of blood products or medication such as **chemotherapy**.

Description

For peripheral venipuncture the common site is usually a vein in the arm (the anticubital fossa located on the opposite side of the elbow) or on the flat bony area of the hand (dorsum of the hand). Scalp veins are accessible in infants under one year of age. The selected vein should be long and straight for needle accommodation. It should be identified by straightness, lack of pulsation (characteristic of an artery), and filling with blood from above (arteries fill from below). Internal jugular catheterization is performed in the neck using special bone and muscle landmarks. The external jugular vein can be cannulized by immobilizing, tilting and rotating the head. The subclavian approach is a complicated procedure and emergency access can be performed if attempts to access a vein in other areas have failed. Intraosseous venous access is usually accomplished through a leg bone. Catheters and subcutaneously implanted ports placed in the front of the chest (anterior chest wall) and other anatomic locations can accomplish long-term venous access as can peripherally inserted central catheters (PICC lines).

Precautions

There are no major precautions for access during emergency procedures. The main concern during an emergency is to secure a portal of entry to infuse potentially life-saving medications and fluids. For all methods of access the main precautionary measures include attention to accurate procedures. Proper procedures are necessary to minimize the possibility of infection, **embolism**, phlebitis, or destruction of neighboring tissue.

Preparation

For peripheral vein access in the arm, a tourniquet is applied a few inches over the puncture site. The skin over the puncture site is cleansed with an alcohol pad or similar cleansing product. The needle is inserted and either blood is drawn and the needle is removed or a catheter is inserted to place an intravenous line. Internal jugular vein catheterization is accomplished by extending the patient's head over the edge of a bed, table or cart and rotating the head away from the intended puncture site. Immobilizing the head and extending it 15–20 degrees over the edge of a bed or cart and rotating away from the puncture site can cannulize the external jugular vein. The subclavian vein access is a complicated procedure and may require sedation and special positioning (Trendelenburg). A towel should be place in the back of the area. The skin should be cleansed and the puncture site anesthetized. For the femoral approach the leg is externally rotated. The artery should be felt and along with specific anatomical landmarks the vein can be localized. The skin should be cleaned and anesthetized. During venous cutdown a large vein near the anklebone is careful dissected away from underlying tissues. The area must be properly cleaned and anesthetized prior to making an incision. A catheter is inserted and secured in place with sutures.

Aftercare

For simple procedures such as peripheral venous access, applying simple pressure (to stop bleeding) once the catheter is removed and then a bandage may be sufficient. Aftercare of more complicated venous access procedures varies depending on the type of device placed and the location of the device.

Risks

For access into a peripheral vein, care must be taken not to puncture both sides of the vein. After removal of the needle or catheter, pressure should be applied over the puncture site to prevent unwanted bleeding. Access utilizing a scalp vein should be performed with care by experienced clinicians only to avoid hematoma formation (localized blood clot), accidental puncture of an artery, or infection. Access into the internal jugular vein in the neck can cause laceration of an artery or nerve. This procedure can also cause hematoma (blood clot) formation, damage to local nerves within the area, pneumothorax, or misplaced catheterization. Venous access into the external jugular vein can cause hematoma or placement of a venous access device outside the thorax.

Subclavian vein access can cause air to enter a vein (resulting in an air embolus) or pneumothorax. Cannulation of the femoral vein in the groin area can cause infection or **thrombophlebitis**. Intraosseous venous access, commonly performed in a leg bone, can cause hematomas, infection, or damage to bone marrow. This procedure should not be performed if the attempts in one leg are unsuccessful, the skin over the legs is diseased (from a burn or infection), or there is a broken leg bone or bone disease. Venous cutdown can cause infection, loss of the catheter in the vein, phlebitis, or nerve damage.

Venous insufficiency

Definition

Venous insufficiency is described as abnormal blood flow through veins that can cause local damage, damage to affected legs, or death.

Description

Syndromes related to venous insufficiency are caused by valve incompetence. Venous insufficiency is a chronic (long term) condition. The number of new and existing cases is dependent on age and gender. Some patients may have a positive family history. Usually older persons and females are more commonly affected. Deep situated and superficial veins can be affected. Cancer obstructing veins in the pelvis area can cause superficial venous insufficiency. Deep venous insufficiency is commonly caused by **thrombophlebitis**, causing obstruction of valves that regulate blood flow in veins. Small veins that have been occluded by a thrombosis may re-canalize (opening up new channels to re-direct blood flow). These re-canalized veins are inadequate and cannot correct the impairment of flow. However, larger veins may still remain occluded. When a thrombosis occurs the valves that regulate venous blood flow become thickened and incompetent, rendering them incapable of regulating back flow of blood. This valvular incompetence will cause an increase in the presence within veins (venous **hypertension**). Venous hypertension is responsible for most of the symptoms associated with venous disease. Superficial veins can become dilated causing **varicose veins** (veins that bulge and seem tortuous). Leg **ulcers** can be severe and are responsible for 100,000 cases of disability in the United States alone.

Causes and symptoms

The symptoms of chronic venous insufficiency can be subjective and objective. Subjective symptoms include throbbing, cramping, burning sensations, and leg **fatigue**. Patients can also develop chronic leg ulcers that may not heal. Varicose veins in the legs can bleed (since veins are delicate structures with thin walls) and cause death. Patients often develop fluid retention (**edema**) in the affected limb. Skin changes can occur and affected areas can become thin, shiny, discolored (blue-purple), and atrophic. The skin usually becomes thick and tough.

Diagnosis

Several techniques are used to diagnose venous disease. Electrical impedance plethysmography (IPG) provides a functional evaluation for outflow obstruction **ultrasound** (a machine that transmits sound waves) studies can visualize the venous system in certain areas. Another technique called duplex scanning can measure velocity within a vein.

Treatment

Periodic elevation of legs and bed rest can help with leg swelling. Patients are advised to avoid prolonged periods of standing or sitting. Wearing compression stockings can also reduce swelling of the leg. Mild skin infections can be treated with compresses, **steroids**, and, if infection is present, with **antibiotics**. Ulcerations can be treated with compresses, possible surgery, special ointments, and a semi-rigid boot that helps improve blood flow. Varicose veins can be treated with elastic stockings. About 15–20% of patients require surgery,

WWW.BOOKBAZ.IR

KEY TERMS

Atrophic—A wasting of cells and tissues.

Thrombophlebitis—Venous inflammation with formation of a thrombus.

Thrombus—A clot in the cardiovascular system (the system that circulates blood throughout the body).

but only after careful evaluation and specialized testing confirms a beneficial value.

Prognosis

The prognosis is variable and depends on the progression of disease, extent of damage, and the presence of other diseases, which may affect the cardiovascular system.

Prevention

Persons who have a strong family history, evidence of disease, and/or those who stand on their legs many hours daily should discuss the option of elastic stocking with their primary clinician.

Ventricular aneurysm

Definition

Ventricular aneurysm is a complication of a **heart attack** (myocardial infarction). It is a ballooning of a section of a blood vessel in the heart that first appears several days or weeks after an acute myocardial infarction.

Description

A myocardial infarction occurs when a section of the heart wall is deprived of blood and dies (undergoes necrosis, or tissue death, and scarring). The heart wall is mainly muscle. It has two ventricles, the right and left ventricles, which pump blood to and from the lungs, and to the body. When part of the heart muscle dies, pumping power from that part of the wall is lost. After a myocardial infarction, the part of the heart wall that did not die must continue pumping blood and compensate for the dead muscle.

Ventricular aneurysm is one of the complications that follow a myocardial infarction.

An aneurysm is the outward swelling, or ballooning, of a blood vessel at a weak spot in the wall of the blood vessel. In the case of ventricular aneurysm, the aneurysm occurs in the wall of the heart at the spot where the myocardial infarction occurred. A scar usually forms in the area of the dead muscle tissue and may eventually calcify. Ventricular aneurysms generally do not rupture. The left ventricle is involved in most cases of ventricular aneurysm.

Causes and symptoms

The principle symptom of a ventricular aneurysm is cardiac insufficiency, a condition in which not enough blood is being pumped to the body. Ventricular aneurysm is usually found after a large infarction in the muscle wall of a ventricle. Ventricular aneurysm is seldom seen immediately after a myocardial infarction. It takes several days or weeks to several months to develop. Frequently, recurrent ventricular irregular heartbeats (**arrhythmias**) and low cardiac output result from the presence of a ventricular aneurysm. **Blood clots** (thrombi) may form on the inside wall of the aneurysm and produce systemic blood clots that get stuck in a blood vessel (embolisms), which could lead to **stroke** or an ischemic leg (a usually painful condition in which lack of blood circulation leads to reduced function).

Diagnosis

A number of signs may indicate ventricular aneurysm, including an abnormal precordial impulse in the heartbeat, persistent elevation of the S-T segment of an electrocardiogram, and a characteristic bulge seen on the heart when x rayed. The bulge is typically seen when the heart contracts, driving blood to the aorta, in the systolic phase of the heartbeat. Echolocation (**echocardiography** or **ultrasound**) can confirm the presence of an aneurysm. **Cardiac catheterization** may be performed to determine the extent of the aneurysm and the status of the coronary arteries. Stethoscopic examination reveals abnormal heart sounds, especially those associated with a backflow of blood from the left ventricle to the left atrium in

KEY TERMS

Arrhythmia—A disturbance in the beating pattern of the heart.

Myocardial infarction—Commonly known as a heart attack, a myocardial infarction occurs when a part of the heart muscle is deprived of blood and dies.

systole or contraction beat (mitral regurgitation). This heart murmur is caused by the heart muscles no longer being able to properly operate the mitral valve.

Treatment

Most cases of ventricular aneurysm are treated by close medical follow-up and limiting patient activity. Surgical removal of the aneurysm is an option when persistent left ventricular failure or arrhythmia occurs, and the aneurysm is large. **Vasodilators**, **diuretics**, and **digoxin** are used to treat **heart failure**. **Anticoagulant drugs** are used to prevent the formation of blood clots. **Antiarrhythmic drugs** are used to treat heart arrhythmias.

Prognosis

Ventricular aneurysm occurs more frequently than is commonly thought. Based on postmortem examination, ventricular aneurysm occurs in as many as 15% of myocardial infarction cases. Patients with a large ventricular aneurysm in the left ventricle have a reduced survival rate. Many patients have mild symptoms which are not life-threatening. The survival rate is dependent on the function of the left ventricle.

Ventricular assist device

Definition

A ventricular assist device (VAD) is a mechanical pump used for temporary blood circulation support. It decreases the workload of the heart while maintaining adequate flow and blood pressure.

Purpose

A VAD is a temporary life-sustaining device. VADs can replace the left ventricle (LVAD), the right ventricle (RVAD), or both ventricles (BIVAD). They are used when the heart muscle is damaged and needs to rest in order to heal or when blood flow from the heart is inadequate. VADs can also be used as a bridge in patients awaiting **heart transplantation** or in patients who have rejected a transplanted heart.

Examples of patients who might be candidates for a VAD are those who:

- have suffered a massive heart attack
- cannot be weaned from heart-lung bypass after treatment with intravenous fluids, medications, and insertion of a balloon pump in the aorta
- have an infection in the heart wall that does not respond to conventional treatment
- are awaiting a heart transplant and are unresponsive to drug therapy and intravenous fluids
- are undergoing high-risk procedures to clear the blockages in a coronary artery

Although one in five people suffer left side ventricular failure, only a minority are candidates for VADs. To be considered for a VAD, patients must meet specific criteria concerning blood flow, blood pressure, and general health.

Precautions

Poor candidates for a VAD include those with:

- irreversible renal failure
- severe disease of the vascular system of the brain
- cancer that has spread (metastasized)
- severe liver disease
- blood clotting disorders
- severe lung disease
- infections that do not respond to antibiotics
- extreme youth or age

Description

There are four types of VADs, each appropriate for a particular condition. Surgery to install a VAD is performed under general **anesthesia** in a hospital operating room. An incision is made in the chest, then catheters are inserted into the heart and the correct artery. The surgeon sutures the catheters in place, then attaches tubing to connect the catheters to the pump. The pump stays outside the body. Once it is turned on, blood flows out of the diseased ventricle

WWW.BOOKBAZ.IR

KEY TERMS

Coronary blood vessels—The arteries and veins that supply blood to the heart muscle.

Diaphragm—The muscle that separates the chest cavity from the abdominal cavity.

Ventricle—The name for one of two chambers at the bottom of the heart, which act as the body's main pumps.

and into the pump, then is returned to the correct blood vessel leaving the heart.

Preparation

Before the operation the patient meets with an anesthesiologist to determine any special conditions that will affect the administration of anesthesia. Standard preoperative blood and urine studies are performed, and the heart is monitored both before and during the operation with an electrocardiograph.

Aftercare

The patient is monitored in intensive care, with follow-up blood, urine, and neurological studies. Blood thinning medications are given to prevent blood clotting.

Except for those patients awaiting a heart transplant, patients are slowly and gradually weaned from the VAD. Even when patients no longer need the VAD, they will require supportive drug therapy and/or a balloon pump inserted in the aorta.

Risks

VAD insertion carries risks of severe complications. Bleeding from surgery is common and occurs in as many as 30–50% of patients. Other complications include the development of **blood clots**, partial **paralysis** of the diaphragm, **respiratory failure**, kidney failure, failure of the VAD, damage to the coronary blood vessels, **stroke**, and infection.

Sometimes when the left ventricle is supported, the right ventricle begins to need assistance. If VADs are inserted in both ventricles, the heart may become so dependent on their support that they cannot be removed.

Results

Because conditions for which VADs are used vary widely and because of the high risks associated with VAD insertion, the outcome of surgery cannot be predicted.

Ventricular ectopic beats

Definition

A ventricular ectopic beat (VEB) is an extra heartbeat originating in the lower chamber of the heart. This beat, also called a premature ventricular contraction (PVC), occurs before the beat triggered by the heart's normal function.

Description

Ventricular ectopic beats are common and do not indicate a problem in people without **heart disease**. However, if a person has aortic stenosis, **heart failure**, or a previous **heart attack**, VEBs may be followed by **ventricular tachycardia** and fibrillation, which can lead to sudden death.

Causes and symptoms

Although the origin of a VEB is well documented, the exact cause or causes are not well understood. Some physicians believe the beat is caused by a trigger of specific origin, while other physicians believe the beat is random. Occasional ventricular ectopic beats occur in healthy people. If there is no evidence of heart disease, there is little or no danger to the individual.

A single ventricular ectopic beat has very little effect on the pumping ability of the heart and usually does not cause any symptoms. If a symptom is felt, it is the feeling of a strong or skipped beat, often described as a thump, kick, or flip-flop. Sometimes, the sensation is referred to as a fullness in the neck.

KEY TERMS

Angioplasty—A surgical procedure which dilates a narrowed or blocked part of an artery.

Aortic stenosis—A stiffening of the artery that carries blood from the heart to the body.

Beta-blockers—A class of medication used to block the cellular response to chemicals normally present in the body.

Coronary artery—The vessel which brings blood to the muscle of the heart.

Fibrillation—Rapid, uncoordinated quivering of the heart.

Heart failure—A term used when the heart is unable to pump enough blood to supply the needs of the body.

Diagnosis

Ventricular ectopic beats are easily seen on an electrocardiogram.

Treatment

If a person is otherwise healthy, the only treatment needed is to decrease **stress** and limit the use of alcohol and **caffeine**. Cold medicines, available without prescription, sometimes contain drugs (e.g., **decongestants**) that stimulate the heart and should be used with caution.

If symptoms are uncomfortable or the pattern of VEBs indicates a problem, the physician may prescribe drug therapy. Beta-blockers are quite safe and are usually tried first.

A person who has a history of heart attack or heart disease and is experiencing frequent or complex VEBs is at greater risk of sudden death. Drug therapy with beta-blockers will be recommended. In addition, **angioplasty** or coronary artery bypass surgery may relieve any underlying coronary artery blockage and reduce the danger of sudden death.

Treatment with **antiarrhythmic drugs** can suppress VEBs, but they can also increase the risk of a fatal abnormal rhythm. Often, extensive electrophysiologic testing and risk evaluation will be done before this method of treatment is prescribed.

Prognosis

In healthy people, VEBs are inconsequential. If a person with heart disease is able to find an effective means of controlling ventricular ectopic beats, the outlook is good.

Prevention

Occasional ventricular ectopic beats in healthy people do not need to be prevented. People with a history of heart disease can usually control VEBs with medication.

Ventricular failure *see* **Heart failure**

Ventricular fibrillation

Definition

Ventricular fibrillation is a very rapid, uncoordinated, ineffective series of contractions throughout the lower chambers of the heart. Unless stopped, these chaotic impulses are fatal.

Description

When the ventricles begin to quiver and do not employ coordinated contractions, the heart is said to be fibrillating. In this condition the ventricles cannot pump blood from the heart. Ventricular fibrillation (V-fib) is the worst kind of abnormal heart rhythm and is a form of cardiac arrest. It involves the pumping of the lower chambers of the heart, while **atrial fibrillation** involves the upper chambers.

Causes and symptoms

Ventricular fibrillation often is associated with acute ischemic events (ischemia involves the deprivation of oxygenated blood to an area of tissue), and with chronic ischemic **heart disease**. It is frequently seen immediately following a **heart attack**. It also may develop during hypoxia, atrial fibrillation, or improper grounding of electrical devices. An extremely low level of potassium in the blood also can cause ventricular fibrillation.

The first, and usually the only, symptom of V-fib is sudden unconsciousness.

WWW.BOOKBAZ.IR

KEY TERMS

Atrial fibrillation—A condition in which the upper chambers of the heart quiver instead of contracting effectively.

Cardiopulmonary resuscitation (CPR)—Using rescue breathing and chest compressions to help a person whose breathing and heartbeat have stopped.

Cardioversion—An electrical shock delivered to the heart to restore a normal rhythm.

Electrocardiogram—A visual representation of the heart beat.

Heart failure—A term used when the heart is unable to pump enough blood to supply the needs of the body.

Hypoxia—Insufficient oxygen in the cells of the body.

Ischemic—Insufficient blood reaching the tissues.

Diagnosis

When an individual suddenly collapses, the possibility of ventricular fibrillation should be considered immediately. A quick assessment usually shows no pulse or heartbeat. The diagnosis of ventricular fibrillation is confirmed with an electrocardiogram.

Treatment

Basic **life support** with standard **cardiopulmonary resuscitation** (CPR) must be started within a few minutes, followed as soon as possible with **cardioversion**. Cardioversion is an electric shock delivered to the heart to stop the fibrillating. Early **defibrillation** is the key to survival. If left untreated, irreversible brain damage, due to lack of oxygen to the brain, occurs after about five minutes. After the heart resumes its normal rhythm, medications are given to help maintain the rhythm.

Research continues into methods to deliver defibrillation as soon as possible to those experiencing ventricular fibrillation. One of the studies addressed in 2003 researched various clinical trials that implanted defibrillators into patients to prevent **sudden cardiac death**. The devices worked in many instances but more proof of their success was needed for widespread use.

Prognosis

Early and effective CPR may provide the time necessary for medical personnel to arrive with a defibrillator. If a defibrillator is able to promptly restore a normal rhythm, up to 25% of victims are able to leave the hospital without evidence of brain damage.

If ventricular fibrillation occurs in the hospital in conjunction with a heart attack, defibrillation has a 95% success rate. If shock and **heart failure** are present at the time, even with immediate defibrillation, only about 30% of those stricken are successfully restored to a normal heart rate.

Prevention

A healthy lifestyle to reduce the risk of heart diseases which lead to ventricular fibrillation is the best prevention. For people who have experienced an episode of V-fib, an internal cardioverter-defibrillator may prevent further episodes.

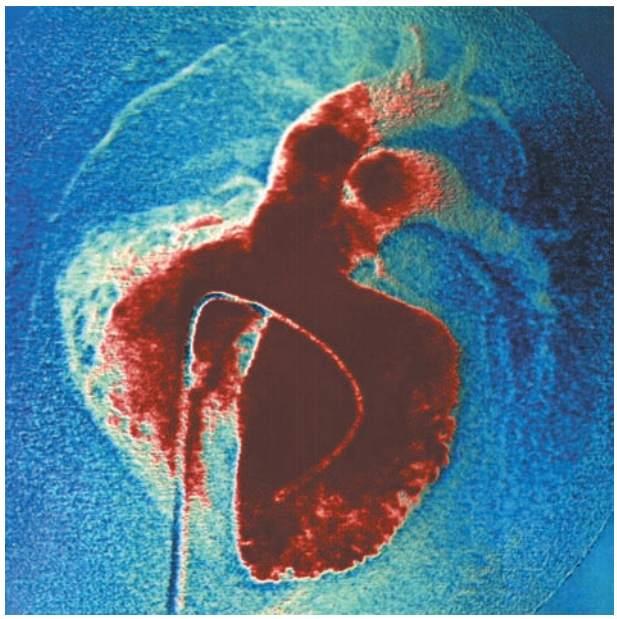
Ventricular septal defect

Definition

A ventricular septal defect is a hole in the wall of the heart (septum) that separates the left lower chamber (left ventricle) from the right lower chamber (right ventricle). The hole allows blood to flow from the left ventricle to the right ventricle instead of entering the aorta for distribution throughout the body. Ventricular septal defect is one of a group of heart problems found in newborn babies that are collectively called **congenital heart disease**.

Description

The heart has four chambers. The two lower chambers are called ventricles and are responsible for pumping blood. The right ventricle pumps blood to

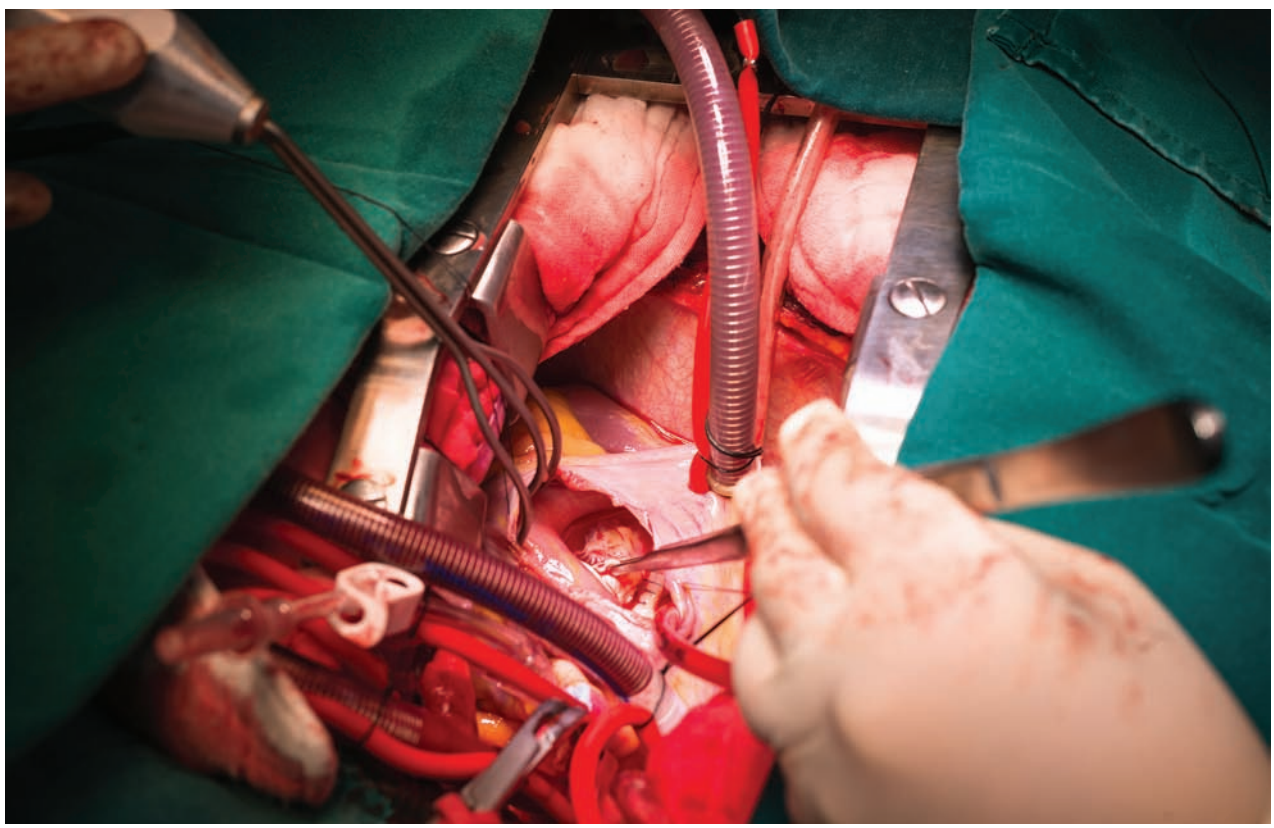


An angiogram of a ventricular septal defect. This is a hole in the ventricular septum causing blood to flow from the left ventricle (right of image) to the right ventricle and to the lungs. *(Simon Fraser/SPL/Photo Researchers, Inc.)*

the lungs and the left ventricle pumps blood throughout the body. If there is a hole in the septum that separates the two ventricles, blood from the left ventricle can enter the right ventricle. This blood recycles through the lungs before returning to the left ventricle. This results in less oxygenated blood reaching the body. If the hole is sufficiently large, the lack of oxygen being delivered to the body can cause severe problems, including **heart failure** and breathlessness. Approximately 0.7% of all babies have a congenital heart defect. Of these, 20% have a ventricular septal defect.

Causes and symptoms

Congenital heart defects are errors in the development of the heart structure. They occur early in the life of the embryo. There is no known cause of congenital heart defects. They can be associated with several diseases, such as German **measles** (rubella)and **Down syndrome**. Genetics does not seem to play a role in ventricular septal defect. People with a heart defect do not have an increased chance of passing it on to their children.



(© ChaNaWiT/Shutterstock.com)

WWW.BOOKBAZ.IR

KEY TERMS

Echocardiogram—An image of the heart produced by an instrument that uses sound waves to create image the heart.

Electrocardiogram—A graph of the heart's beating action.

Endocarditis—An inflammation of the interior lining of the heart that is frequently caused by infectious agents.

Symptoms result from a reduced amount of oxygen going to the body. Symptoms are proportional to the size of the defect. They may appear at any time in the life of the child. In cases where the hole in the septum is very small, few or no symptoms may appear and the child may develop normally. In cases where the ventricular septal defect is large, the newborn will shows signs of heavy breathing, sweating, and feeding difficulties. Children with this defect tire easily. Ventricular septal defect can also result in stunted growth resulting from insufficient oxygen being delivered to the growing body. Children with ventricular septal defect tend to suffer more frequent colds and **pneumonia**, and have a higher rate of inflammation and infection of the heart (**endocarditis**).

Diagnosis

The condition is first suspected based on observation of the child. The physician will listen to the heart with a stethoscope (auscultation) to detect a heart murmur. X rays, electrocardiogram (ECG), and **echocardiography** can all be used to evaluate ventricular septal defect.

Treatment

Most small holes close without treatment. Often, as the child grows, the hole closes or becomes smaller. If the hole is large or fails to close, the child is usually treated with drugs. Holes that persist and are causing problems in development are corrected by open heart surgery. Usually, surgery is performed after one year of age, but before the child enters school. This allows time for a trial of drug therapy, which could potentially eliminate the need for surgery. The operation is generally safe.

Prognosis

Children with small septal defects tend to develop normally and without any effect on their ability to participate in physical activities. Surgery allows children with larger defects to live nearly normal lives.

Ventricular shunt

Definition

Ventricular shunt is a surgical procedure in which a tube is placed in one of the fluid-filled chambers inside the brain (ventricles). The fluid around the brain and the spinal column is called the cerebrospinal fluid. When infection or disease causes an excess of this cerebrospinal fluid in the ventricles, the shunt is placed to drain it and thereby relieve excess pressure.

Purpose

Ventricular shunt relieves **hydrocephalus**, a condition in which the ventricles are enlarged. In hydrocephalus, pressure from the cerebrospinal fluid usually increases. It may be caused by tumor of the brain or of the membranes covering the brain (meninges), infection of or bleeding into the cerebrospinal fluid, or inborn malformations of the brain. Symptoms of hydrocephalus may include **headache**, personality disturbances and loss of intellectual abilities (**dementia**), problems in walking, irritability, **vomiting**, abnormal eye movements, or a low level of consciousness.

Normal pressure hydrocephalus is associated with progressive dementia, problems in walking, and loss of bladder control (**urinary incontinence**). Even though the cerebrospinal fluid is not thought to be under increased pressure in this condition, it may also be treated by ventricular shunting.

Precautions

As with any surgical procedure, the surgeon must know about any medications or health problems that may increase the patient's risk. Because infections are both common and serious complications, **antibiotics** are often given before and after surgery.

Description

The ventricular shunt tube is placed to drain fluid from the ventricular system in the brain to the cavity of the abdomen or to the large vein in the neck (jugular

vein). Therefore, surgical procedures must be done both in the brain and at the drainage site. The tubing contains valves to insure that fluid can only flow out of the brain and not back into it. The valve can be set at a desired pressure to allow cerebrospinal fluid to escape whenever the pressure level is exceeded.

A small reservoir may be attached to the tubing and placed under the scalp. This reservoir allows samples of cerebrospinal fluid to be removed with a syringe to check the pressure. Fluid from the reservoir can also be examined for bacteria, cancer cells, blood, or protein, depending on the cause of hydrocephalus. The reservoir may also be used to inject antibiotics for cerebrospinal fluid infection or **chemotherapy** medication for meningeal tumors.

Preparation

The diagnosis of hydrocephalus should be confirmed by diagnostic techniques that make images of the brain, such as computed tomography scan (CT scan) or **magnetic resonance imaging** (MRI), before the shunting procedure is performed. These techniques will also show any associated brain abnormalities. Cerebrospinal fluid should be examined if infection or tumor of the meninges is suspected. Patients with dementia or intellectual disabilities (ID) should undergo **neuropsychological testing** to establish a baseline psychological profile before the shunting procedure.

Patients with normal pressure hydrocephalus may experience a temporary improvement in walking and mental abilities upon removal of a moderate amount of cerebrospinal fluid. This improvement may be an indication that shunting will improve their condition. However, patients who do not improve after temporary cerebrospinal fluid drainage may still benefit from ventricular shunt. When a case is in doubt, continuous monitoring of cerebrospinal fluid pressure (which in itself requires a surgical procedure) may indicate whether shunting is likely to be helpful.

Aftercare

To avoid infections at the shunt site, the area should be kept clean. Cerebrospinal fluid should be checked periodically by the doctor to be sure there is no infection or bleeding into the shunt. Cerebrospinal fluid pressure should be checked to be sure the shunt is operating properly. The eyes should be examined regularly because shunt failure may damage the nerve to the eyes (optic nerve). If not treated promptly, damage to the optic nerve causes irreversible loss of vision. Patients or caregivers should understand the life-threatening nature of shunt problems. All symptoms and signs of potential shunt failure or infection must be taken seriously.

KEY TERMS

Cerebrospinal fluid—Fluid bathing the brain and spinal cord.

Computed tomography (CT) scan—An imaging technique in which cross-sectional x rays of the body are compiled to create a three-dimensional image of the body's internal structures.

Dementia—Progressive loss of mental abilities.

Magnetic resonance imaging (MRI)—An imaging technique that uses a large circular magnet and radio waves to generate signals from atoms in the body. These signals are used to construct images of internal structures.

Risks

Complications of shunting occur in 30% of cases, but only 5% are serious. Serious and long-term complications are bleeding under the outermost covering of the brain (**subdural hematoma**), infection, **stroke**, and shunt failure. Infection at the shunt site may cause a loss of intelligence. When shunts drain to the abdomen (ventriculoperitoneal shunts), fluid may accumulate in the abdomen or abdominal organs may be injured. If cerebrospinal fluid pressure is lowered too much, patients may have severe headaches, often with **nausea and vomiting**, whenever they sit up or stand.

Results

Of patients with normal pressure hydrocephalus who are treated with shunting, 25–80% experience long-term improvement. Normal pressure hydrocephalus is more likely to improve when it is caused by infection of or bleeding into the cerebrospinal fluid than when it occurs without an underlying cause. Walking difficulties and bladder control are more likely to improve than dementia is.

After shunting, the ventricles get smaller within three or four days. This shrinkage occurs even when hydrocephalus has been present for a year or more. Clinically detectable signs of improvement occur within a few weeks. The cause of hydrocephalus, duration of hydrocephalus before shunting, and associated brain abnormalities affect the outcome.

Laurie Barclay, MD

Ventricular tachycardia

Definition

Ventricular tachycardia (V-tach) is a rapid heart beat that originates in one of the lower chambers (the ventricles) of the heart. To be classified as tachycardia, the heart rate is usually at least 100 beats per minute.

KEY TERMS

Atrial—Having to do with the upper chambers of the heart.

Cardiomyopathy—A disease of the heart muscle.

Cardioversion—A electrical shock delivered to the heart to restore a normal rhythm.

Coronary artery—The artery that supplies blood to the heart muscle itself.

Electrocardiogram—A visual representation of the heart beat.

Fibrillation—Rapid, uncoordinated, quivering of the heart.

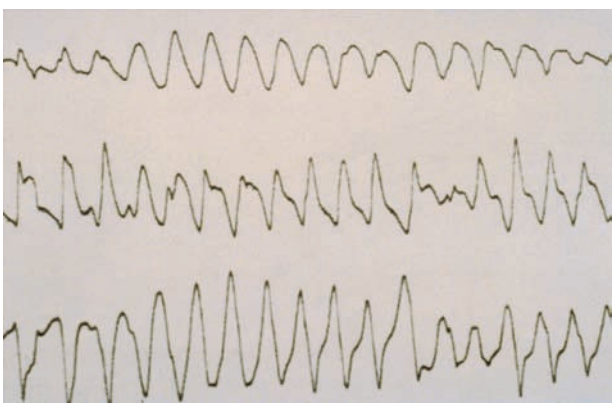
Palpitations—Uncomfortable feeling of the heart beat in the chest.

Valvular—Having to do with the valves inside the heart.

Description

A rapid heart rate can originate in either the left or right ventricle. Ventricular tachycardia which lasts more than 30 seconds is referred to as sustained ventricular tachycardia. A period of three to five rapid beats is called a salvo, and six beats or more lasting less than 30 seconds is called nonsustained ventricular tachycardia. Rapid ventricular rhythms are more serious than rapid atrial rhythms because they make the heart extremely inefficient. They also tend to cause more severe symptoms, and have a much greater tendency to result in death.

Although generally considered to be among the life-threatening abnormal rhythms, harmless forms of sustained V-tach do exist. These occur in people without any structural **heart disease**.



An electrocardiographic image indicating a rapid heart beat. *(Custom Medical Stock Photo, Inc.)*

Causes and symptoms

Most ventricular tachycardias are associated with serious heart disease such as coronary artery blockage, **cardiomyopathy**, or **valvular heart disease**. V-tach is often triggered by an extra beat originating in either the right or left ventricle. It also occurs frequently in connection with a **heart attack**. V-tach commonly occurs within 24 hours of the start of the attack. It must be treated quickly to prevent fibrillation. After 48–72 hours of the heart attack, the risk of ventricular tachycardia is small. However, people who have suffered severe damage to the larger anterior wall of the heart have a second danger period, because V-tach often occurs during convalescence from this type of heart attack.

Sustained ventricular tachycardia prevents the ventricles from filling adequately so the heart can not pump normally. This results in loss of blood pressure, and can lead to a loss of consciousness and to **heart failure**.

The individual with V-tach almost always experiences palpitation, though some episodes cause no symptoms at all.

Diagnosis

Diagnosis is easily made with an electrocardiogram.

Treatment

Any episode of ventricular tachycardia that causes symptoms needs to be treated. An episode that lasts more than 30 seconds, even without symptoms, also needs to be treated. Drug therapy can be given

intravenously to suppress episodes of V-tach. If blood pressure falls below normal, a person will need electric **cardioversion** ("shock") immediately.

Prognosis

With appropriate drug or surgical treatment, ventricular tachycardia can be controlled in most people.

Prevention

A person susceptible to sustained ventricular tachycardia often has a small abnormal area in the ventricles that is the source of the trigger event. This area can sometimes be surgically removed. If surgery is not an option, and drug therapy is not effective, a device called an automatic cardioverter-defibrillator may be implanted.

Vertical banded gastroplasty

Definition

Vertical banded gastroplasty (VBG) is an elective surgical procedure in which the stomach is partitioned with staples and fitted with a plastic band to limit the amount of food that the stomach can hold at one time. Gastroplasty is a term that comes from two Greek words: *gaster*, or "stomach," and *plassein*, which means "to form or shape." Also known as stomach stapling, VBG is part of a surgical subspecialty called **bariatric surgery**. VBG is considered a restrictive bariatric procedure, since it controls the amount of food that the stomach can hold. Malabsorptive bariatric procedures, in contrast, reroute food within the digestive tract to prevent complete absorption of the nutrients.

Purpose

The purpose of VBG is the treatment of morbid **obesity**. It was one of the first successful procedures in bariatric surgery. VBG was developed in its present form in 1982 by Dr. Edward E. Mason, a professor of surgery at the University of Iowa.

Bariatric surgery in general has demonstrated long-term success in the majority of patients. Weight-reduction **diets**, **exercise** programs, and appetite-suppressant medications have had a low long-term success rate in managing morbid obesity. Most people who try to lose weight on reduced-calorie diets regain two-thirds of the weight lost within one year; within five years, they have gained more weight in addition to all the weight they had lost previously. Appetite suppressants often have undesirable or harmful side effects, as well as having a low rate of long-term effectiveness; in 1997, the U.S. Food and Drug Administration (FDA) banned the sale of fenfluramine and phentermine ("fen-phen") when these substances were discovered to cause damage to heart valves.

Obesity is a major health problem not only because it is widespread in the American population—more than one-third of adults in the United States meet the National Institutes of Health (NIH) criteria for obesity—but because it greatly increases a person's risk of developing potentially life-threatening disorders. Obesity is associated with type 2 diabetes, **hypertension**, abnormal blood **cholesterol** levels, **liver disease**, **coronary artery disease**, **sleep apnea** syndrome, depression, **urinary incontinence**, and certain types of cancer. In addition to these disorders, obesity is a factor in what has been called lifestyle-limiting conditions. These conditions are not life-threatening, but they can have an enormous impact on people's day-to-day lives, particularly in their relationships and in the working world. Lifestyle-limiting conditions related to obesity include **osteoarthritis** and **gout**, urinary **stress** incontinence, **heartburn**, skin disorders caused by heavy perspiration accumulating in folds of skin, leg swelling and **varicose veins**, **gallstones**, and abdominal hernias. Women who are obese frequently suffer from irregular menstrual periods and **infertility**. Finally, societal prejudice against obesity may contribute to acute psychological distress. Surgical treatment of obesity has been demonstrated to relieve emotional **pain** as well as to reduce risks to the patient's physical health.

Demographics

Data from 2011 stated that more than one-third of U.S. adults (35.7%) were obese; however, VBG is performed only on patients who are severely or morbidly obese by NIH standards. Severe obesity is presently defined as a **body mass index** (BMI) of 35 or higher. BMI is a ratio of the weight and height calculated by a specific formula. Obesity is the epidemic with the greatest prevalence in the United States. In 2008, obesity among men was generally similar at all income levels, with a tendency to be slightly higher at

WWW.BOOKBAZ.IR

KEY TERMS

Appetite suppressant—A medication given to reduce the desire to eat.

Bariatrics—The branch of medicine that deals with the prevention and treatment of obesity and related disorders.

Body mass index (BMI)—A measurement that has replaced weight as the preferred determinant of obesity. The BMI can be calculated (in American units) as 703.1 times a person's weight in pounds divided by the square of the person's height in inches.

Comorbid—A term applied to a disease or disorder that occurs at the same time as another disease condition. There are a number of health problems that are comorbid with obesity.

Dehiscence—A separation or splitting apart. In a vertical banded gastroplasty, dehiscence refers to the coming apart of the line of staples used to form the stomach pouch.

Gastric pacing—An experimental form of obesity surgery in which electrodes are implanted in the muscle of the stomach wall. Electrical stimulation paces the timing of stomach contractions so that the patient feels full on less food.

Hernia—The protrusion of tissue or an organ through an incision, weakened area, or abnormal opening into other tissues or outside of a cavity. Incisional hernias sometimes occur after open VBGs.

Laparoscope—An instrument that allows a doctor to look inside the abdominal cavity. A less invasive form of VBG can be performed with the help of a laparoscope.

Malabsorptive—A type of bariatric surgery in which a part of the stomach is partitioned off and connected to a lower portion of the small intestine in order to reduce the amount of nutrients that the body absorbs from food.

Morbid—Unwholesome or bad for health. Morbid obesity is a condition in which weight presents a very high risk to the patient's health. The NIH (National Institutes of Health) prefers the term "severely obese" to "morbidly obese."

Obesity—Excessive weight gain due to accumulation of fat in the body, sometimes defined as a BMI (body mass index) of 30 or higher, or body weight greater than 30% above a person's desirable weight on standard height-weight tables.

Prevalence—The number of cases of a disease or disorder that are present in a given population at a specific time.

Restrictive—A type of bariatric surgery that works by limiting the amount of food that the stomach can hold. Vertical banded gastroplasty is a restrictive procedure.

Sleep apnea syndrome—A disorder in which the patient's breathing temporarily stops at intervals during the night due to obstruction of the upper airway. People with sleep apnea syndrome do not get enough oxygen in their blood and often develop heart problems.

Stricture—An abnormal narrowing of a body canal or opening. Sometimes strictures form near the plastic band in a VBG. A stricture may also be called an area of stenosis.

higher income levels. Higher income women are less likely to be obese than low income women. According to a report from the U.S. Centers for Disease Control and Prevention, obesity may become a leading cause of mortality in the United States with an estimated 500,000 deaths per year. During the past 20 years, there has been a dramatic increase in obesity in the United States. In 2008, medical costs associated with obesity were estimated at $147 billion. Non-Hispanic blacks have the highest age-adjusted rates of obesity (49.5%), compared with Mexican Americans (40.4%), all Hispanics (39.1%) and non-Hispanic whites (34.3%). In 2011, individual state data concluded that obesity prevalence ranged from 20.7% in Colorado to 34.9% in Mississippi. No individual state had a prevalence of obesity less than 20%. According to the American Society for Metabolic and Bariatric Surgery (ASMBS), formerly known as the American Society for Bariatric Surgery (ASBS), while the prevalence of obesity in the United States doubled between 1986 and 2000, the prevalence of morbid obesity quadrupled and the prevalence of super-obesity increased fivefold.

In the United States, the number of **gastric bypass** surgeries increased by more than 600% from 1993 to 2003. Between 2004 and 2006, more than 16,000 laparoscopic gastric bypass procedures and 6,000 gastric bypass procedures were performed. According to one study from the Agency for Healthcare Research and Quality (AHRQ), the mortality rate associated with bariatric surgery dropped by a staggering 78.7%, from 0.89% in 1998 to 0.19% in 2004. The mortality

rate from morbid obesity was reduced by 89% after bariatric or metabolic surgery, according to a study published in the Annals of Surgery in 2004.

Description

A VBG is performed in a hospital regardless of whether the operation is an open or a laparoscopic gastroplasty. It is done by a bariatric surgeon, who is a medical doctor (MD) or doctor of **osteopathy** (DO) who has completed at least three years' training in **general surgery** after medical school and internship. Most bariatric surgeons have had additional training in gastrointestinal or biliary surgery before completing a fellowship in bariatric surgery with an experienced practitioner in this subspecialty.

In addition to demonstrating the technical skills necessary to perform a VBG, bariatric surgeons seeking hospital privileges must show that they are competent to provide the psychological and nutritional assessments and counseling included in weight loss surgery programs.

There are two major types of VBG—open, which is the older of the two procedures; and laparoscopic, which is performed through very small incisions with the help of special instruments. Based on results of observational studies and small randomized controlled trials (RCTs), laparoscopic or minimally invasive techniques are thought to reduce potential complications and be safer for patients. Patients also have a faster recovery time with minimally invasive techniques.

Open vertical banded gastroplasty

The open VBG is done under general **anesthesia**. In most cases, it takes one to two hours to perform. The surgeon makes an incision several inches long in the patient's upper abdomen. After cutting through the layers of tissue over the stomach, the surgeon cuts a hole, or "window," into the upper part of the stomach a few inches below the esophagus. The second step involves placing a line of surgical staples from the window in the direction of the esophagus, which creates a small pouch at the upper end of the stomach. The surgeon must measure the size of this pouch very carefully; when completed, it is about 10% of the size of a normal stomach and will hold about a tablespoon of solid food.

After forming the pouch and checking its size, the surgeon takes a band made out of polypropylene plastic and fits it through the window around the outlet of the stomach pouch. The vertical band is then stitched into place. Because the polypropylene does not stretch, it holds food in the stomach longer, which allows the patient to feel full on only a small amount of food.

Following the placement of the band, the surgeon will check to make sure that there is no leakage around the window and the line of surgical staples. The area of surgery will then be washed out with a sterile saline solution and the incision closed.

Laparoscopic vertical banded gastroplasty

A laparoscopic vertical banded gastroplasty, or LVBG, is performed with the help of a bariatric laparoscope. A laparoscope is a small tube, 0.39 in. (10 mm) in diameter, that holds a fiberoptic cable that allows the surgeon to view the inside of the abdominal cavity on a high-resolution video screen and record the operation on a video recorder. In a laparoscopic VBG, the surgeon makes three small incisions on the left side of the abdomen for inserting the laparoscope, and a fourth incision about 2.5 in. (14 cm) long on the right side. The formation of the stomach pouch and insertion of the plastic band are done through these small incisions. Because it is more difficult for the surgeon to maneuver the instruments through the small openings, an LVBG takes longer than an open VBG, about two to four hours.

A laparoscopic VBG requires that the surgeon spend more time training than with an open VBG. In the event of complications developing during a laparoscopic VBG, the surgeon usually completes the operation using the open procedure.

Diagnosis

Determination of obesity

The diagnosis of a patient who is considered to be eligible for bariatric surgery begins with measuring the degree of the patient's obesity. This measurement is crucial because the NIH and almost all health insurers have established specific limits for approval of bariatric procedures.

The obesity guidelines that are cited most often were drawn up by Milliman and Robertson, a nationally recognized company that establishes medical need for a wide variety of procedures for health insurers. The Milliman and Robertson criteria for weight-loss surgery specifies patients who:

- are at least 100 lb. (45 kg) over ideal weight, as defined by life insurance tables; have a BMI of 40 or higher; or have a BMI over 35 with a coexisting serious medical condition, such as diabetes or coronary artery disease
- demonstrate failure to lose weight or a tendency to regain weight despite having tried a multidisciplinary weight-control program

WWW.BOOKBAZ.IR

- have another cause of obesity, such as an endocrine disorder
- have attained full adult height

The patient must be treated not only by a doctor with special training in obesity surgery, but in a comprehensive program that includes: preoperative psychological screening and medical examination; nutritional counseling; exercise counseling; and participation in support groups.

There are several ways to measure obesity. Some are based on the relationship between a person's height and weight. The older measurements of this correlation are the so-called height-weight tables that listed desirable weights for a given height. The limitation of height-weight tables is that they do not distinguish between the weight of human fatty tissue and the weight of lean muscle tissue—many professional athletes and bodybuilders are overweight by the standards of these tables. A more accurate measurement of obesity is body mass index, or BMI. The BMI is an indirect measurement of body fat. The BMI is calculated in American measurements by multiplying a person's weight in pounds by 703.1, then dividing that number by the person's height in inches squared. A BMI between 19 and 24 is considered normal; 25–29 is overweight; 30–34 is moderately obese; 35–39 is severely obese; 40 or higher is defined as morbidly obese; and 50 or higher is super-obese.

More direct methods of measuring body fat include measuring the thickness of the skinfold at the back of the upper arm, and bioelectrical impedance analysis (BIA). Bioelectrical impedance measures the total amount of water in the body, using a special instrument that calculates the different degrees of resistance to a mild electrical current in different types of body tissue. Fatty tissue has a higher resistance to the current than body tissues containing larger amounts of water. A higher percentage of body water indicates a greater amount of lean tissue.

Psychological evaluation

Psychiatric and psychological screening before a VBG is done to evaluate the patient's emotional stability and to ensure that weight loss expectations are not unrealistic. Because of social prejudice against obesity, some obese people who have felt isolated from others or suffered job discrimination come to think of weight loss surgery as a magical or quick solution to all the problems in their lives. In addition, the surgeon will want to make sure that the patient understands the long-term lifestyle adjustments that are necessary after surgery and that the patient is committed to making those changes. A third reason for a psychological assessment before a VBG is to determine whether the patient's eating habits are compulsive. These would be characterized by the persistent and irresistible impulse to eat from unknown or unconscious purposes. Compulsive eating is not a reason for not having weight loss surgery, but it does mean that the psychological factors contributing to the patient's obesity will also require treatment.

Other tests and examinations

Patients must have a complete **physical examination** and blood tests before being considered for a VBG. Some bariatric surgeons will not accept patients with any of the following: histories of major psychiatric illness; alcohol or drug abuse; previous abdominal surgery; or collagen vascular diseases, which include **systemic lupus erythematosus** (SLE) and **rheumatoid arthritis**. Many will not accept patients younger than 16 or older than 55, although some surgeons report successful VBGs in patients over 70. In any event, patients will need to provide documentation of their physical condition, particularly comorbid diseases or disorders, to their insurance company.

Preparation

Preparation for bariatric surgery requires more attention to certain matters than most other forms of surgery requiring hospitalization.

Health insurance issues

Both bariatric surgeons and people who have had weight loss surgery report that obtaining preauthorization for a VBG from insurance companies is a lengthy, complicated, and frequently frustrating process. Insurance companies tend to reflect the prejudices against obese people that exist in the wider society. In addition, bariatric surgery is expensive—between $20,000 and $35,000 per procedure, according to the National Institutes of Health. Although this situation is slowly changing because of increasingly widespread recognition of the high costs of obesity-related diseases, people considering a VBG should contact their insurance provider early to secure approval for their operation.

Lifestyle changes

A VBG requires a period of recovery at home after **discharge from the hospital**. Since the patient's physical mobility will be limited, the following should be done before the operation:

- Arrange for leave from work, assistance at home, help with driving, and similar tasks and commitments.

- Obtain a handicapped parking permit.
- Check the house or apartment thoroughly for needed adjustments to furniture, appliances, lighting, and personal conveniences; specific recommendations include the purchase of a shower chair and toilet seat lift. People recovering from bariatric surgery must minimize bending, stooping, and any risk of falling.
- Stock up on prescription medications, nonperishable groceries, cleaning supplies, and similar items to minimize the need to go shopping. Food items should include plenty of clear liquids (juices, broth, soups) and soft foods (oatmeal and other cooked cereals, gelatin dessert mixes).
- Have a supply of easy-care clothing with elastic waistbands and simple fasteners. Shoes should be slip-ons or fastened with Velcro.
- Take "before" photographs prior to the operation, and make a written record of body measurements. These should include measurements of the neck, waist, wrist, widest part of the hips, bust or chest, knees, and ankles, as well as shoe size. The pre-operation photographs and measurements help to document the rate and amount of weight lost. Patients who have had weight loss surgery also point out that these records serve to boost morale by allowing the patient to measure progress in losing weight after the surgery.

Pre-operation classes and support groups

In line with the Milliman and Robertson guidelines, most bariatric surgeons now have "pre-op" classes and ongoing support groups for patients scheduled for VBG and other types of bariatric surgery. Facilitators of these classes can answer questions regarding preparation for the operation and what to expect during recovery, particularly about changes in eating patterns. In addition, they provide opportunities for patients to share concerns and experiences. Patients who have attended group meetings for weight loss surgery often report that simply sharing accounts of the effects of severe obesity on their lives strengthened their resolve to have the operation. In addition, clinical studies indicate that patients who have attended pre-op classes are less anxious before surgery and generally recover more rapidly.

Medical preparation

Patients scheduled for a gastroplasty are advised to eat lightly the day before surgery. The surgeon will provide specific instructions about taking medications prescribed for other health conditions. The patient will be given pre-operation medications that usually include a laxative to clear the lower digestive tract, an antinausea drug, and an antibiotic to lower the risk of infection. Some surgeons ask patients to shower on the morning of their surgery with a special antiseptic skin cleanser.

Aftercare

Aftercare following a gastroplasty has long-term as well as short-term aspects.

Short-term aftercare

Patients who have had an open VBG usually remain in the hospital for four to five days after surgery; those who have had a laparoscopic VBG may return home after two to three days. Aftercare in the hospital typically includes:

- Pain medication. After returning from surgery, patients are given a patient-controlled anesthesia, or PCA device. The PCA is a small pump that delivers a dose of medication into the IV when the patient pushes a button.
- Clear fluids. Inpatient food is limited to a liquid diet following a VBG.
- Oxygen treatment and breathing exercises to get the patient's lungs back into shape. Patients are encouraged to get out of bed and walk around as soon as possible to prevent pneumonia.
- Regular change of surgical dressings. Patients may be given additional dressings for use at home, if needed.

Long-term aftercare

Long-term aftercare includes several adjustments to the patient's lifestyle:

- Slow progression from consuming liquids to eating a normal diet. For the first two weeks after surgery, the patient is limited to liquids and foods that have been pureed in a blender. The reintroduction of solid foods takes place gradually over several months. In addition, patients sometimes have unpredictable reactions to specific foods, although most of these resolve over time.
- Lifelong changes in eating habits. Patients who have had a VBG must learn to chew food thoroughly and to eat slowly to reduce the risk of nausea and vomiting. They must also be careful to avoid eating too many soft foods or sweets, to reduce the risk of regaining weight.
- A minimum of five years of follow-up visits to the surgeon to monitor weight maintenance and other

WWW.BOOKBAZ.IR

health concerns. Patients considering bariatric surgery should choose a surgeon with whom they feel comfortable, as they are making a long-term commitment to aftercare with this professional.

- Ongoing support group meetings to deal with the physical and psychological aftereffects of surgery and weight loss.
- Beginning and maintaining an appropriate exercise program.

Risks

Patients who undergo a VBG are at risk for some of the same complications that may follow any major operation, including death, **pulmonary embolism**, the formation of **blood clots** in the deep veins of the leg, and infection of the surgical incision. These risks are increased for severely obese patients; for example, the risk of infection is about 10% for obese patients compared to 2% for patients of normal weight. With specific regard to VBGs, recent studies indicate that the risks of complications after surgery are about the same for open and laparoscopic VBGs. The ASMBS reported in 2005 that about 5% of VBGs result in complications, and that the mortality rate is 0.1%.

Specific risks of VBGs

Specific risks associated with vertical banded gastroplasty include:

- Incisional hernia. An incisional hernia is the protrusion of tissue through an incision. It results from the stress placed on the stitches holding the incision closed in extremely obese patients. Most can be repaired by resuturing the incision. Incisional hernias are more likely to occur with open VBGs than with laparoscopic procedures.
- Dehiscence. Dehiscence is the medical term for splitting open; it can occur in a VBG if the staples forming the pouch at the upper end of the stomach come loose.
- Nausea and vomiting. Nausea and vomiting usually result from eating more food than the stomach pouch can hold, or eating the food too quickly. In most cases, the vomiting disappears as the patient learns different eating habits.
- Formation of a stricture at the site of the plastic band. A stricture is an abnormal narrowing of a body canal or opening. It is also called a stenosis.
- Lodging of a food particle, pill, or capsule within the band or ring. If the object does not move further down the digestive tract within 24 hours, it must be removed by an endoscope.
- Damage to the spleen. The spleen lies very close to the stomach and can be injured in the process of bariatric surgery. In most cases, it can be repaired during the operation.

Long-term risks

The long-term risks of vertical banded gastroplasty include:

- Regaining weight. Patients who have had a VBG are more likely to regain lost weight than those who have had gastric bypass surgery. This is partly because the patient's digestive tract continues to absorb the nutrients in food in normal fashion. Because the stomach pouch in a VBG is small, many patients are tempted to eat ice cream and high-calorie liquids that pass quickly through the pouch. A 10-year follow-up study of 70 patients who had a VBG found that only 20% of the patients had lost and kept off the loss of 50% of their excess body weight.
- Ongoing vomiting and heartburn. About 20% of patients with VBGs report long-term digestive difficulties.
- Psychological problems. Some people have difficulty adjusting to the changes in their outward appearance and to others' changed reactions to them. Other patients experience feelings of depression, which are thought to be related to biochemical changes resulting from the weight loss.

Results

The most rapid weight loss following a VBG takes place in the first six months. It usually takes between 18 and 24 months after the operation for patients to lose 50% of their excess body weight, which is the measurement used to define success in bariatric surgery. At this point, most patients feel much better physically and psychologically; diabetes, high blood pressure, urinary stress incontinence, and other complications associated with severe obesity have either improved or completely resolved.

The primary drawback of VBG is its relatively high rate of failure in maintaining the patient's weight loss over a five-year period. The most common form of revision surgery for a failed VBG is the Roux-en-Y gastric bypass. For this reason, some bariatric surgeons recommend VBGs for patients at the lower end of the severe obesity spectrum; that is, those with BMIs between 35 and 40. The chief advantage of VBGs over malabsorptive types of weight loss surgery is that there is little risk of **malnutrition** or vitamin deficiencies.

Although bariatric surgeons advise patients to wait for two years after a VBG to have **plastic surgery** procedures, it is not unusual for patients to require operations to remove excess skin from the upper arms, abdomen, and other parts of the body that had large accumulations of fatty tissue.

Morbidity and mortality rates

According to the American Society of Bariatric Surgery, the rates of postsurgical complications are about 2% for leaks leading to infection and a need to reoperate; 1.5% for dehiscence; 1% for injury to the spleen; and 1% for pulmonary embolisms.

Alternatives

Established surgical alternatives

The primary restrictive alternative to a VBG is implanting a Lap-Band, which is an adjustable band that the surgeon positions around the upper end of the stomach to form the small pouch instead of using staples. The Lap-Band was approved by the U.S. Food and Drug Administration (FDA) for use in the United States in 2001. It can be implanted with the laparoscopic technique. When the band is in place, it is inflated with saline solution. It can be tightened or loosened after the operation through a portal under the skin. Although the Lap-Band eliminates the risk of dehiscence, it produces such side effects as **vomiting**, heartburn, abdominal cramps, or enlargement of the stomach pouch due to the band slipping out of place. In one American study, 25% of patients eventually had the band removed.

The other major type of obesity surgery combines restriction of the size of the stomach with a malabsorptive approach. The combination surgery that is considered the safest and performed most frequently in the United States is the Roux-en-Y gastric bypass. In this procedure, the surgeon forms a stomach pouch and then divides the small intestine, connecting one part of it to the new pouch and reconnecting the other portion to the intestines at some distance from the stomach. The food bypasses the section of the stomach and the small intestine, where most nutrients are absorbed. The procedure takes its name from Cesar Roux, the Swiss surgeon who first performed it, and the "Y" shape formed by the reconnected intestines.

Experimental procedures

A newer technique in obesity surgery is known as gastric pacing or implantable gastric stimulation (IGS). In IGS, the surgeon implants electrodes in the muscle of the stomach wall that deliver a mild electrical current. These electrical impulses regulate the pace of stomach contractions so that the patient feels full on smaller amounts of food. Preliminary results from a team of Italian researchers on patients followed since 1995 indicate that gastric pacing is both safe and effective; studies in the United States have found similar results.

Another experimental surgical alternative in obesity surgery is staged surgery. This approach involves a first-stage less invasive procedure—usually a Lap-Band—that helps patients reduce their weight to a safer level. Once the patient has lost some weight, the more complex Roux-en-Y gastric bypass is performed.

Vertical infections

Definition

Vertical infections, also called mother-to-child infections, are infections transmitted from the mother to her baby, either across the placenta during fetal development (prenatal), during labor or passage through the birth canal (perinatal), or possibly through **breastfeeding**.

Description

Antibodies in the mother's blood prevent most infections from being transmitted to the fetus. However, vertical infections—particularly in the first trimester of pregnancy—may cause **miscarriage** or severe **birth defects**. Other infections can cause preterm labor, fetal or neonatal death, or serious illness in newborns. Perinatal transmissions infect the fetus after its protective membranes rupture (the mother's waters break) or during labor and delivery when the fetus is exposed to maternal blood. Vertical transmission is more likely if waters break prematurely. Pregnant women are at increased risk for getting some foodborne infections because of the hormonal changes that occur during **pregnancy** which suppress the immune system.

Toxoplasmosis

Up to one-third of the world's population is infected with the parasite *Toxoplasma gondii* that causes **toxoplasmosis**. The U.S. Centers for Disease Control and Prevention (CDC) estimates that 25–45% of women of childbearing age carry the parasite, although very few have symptoms, and most pregnant women have antibodies that protect the fetus from infection. However, in about one-third of women who are infected for the first time during pregnancy, the parasite infects the placenta and enters fetal circulation. Congenital (present at birth) infection occurs in one out of every 800–1,400 infants born to infected mothers. The fetal infection rate is above 60% if infection occurs during the third trimester, but the most severe fetal complications occur with first-trimester infections.

Cytomegalovirus (CMV)

CMV is the most common vertical infection. Although 50–80% of women have been infected by CMV prior to pregnancy, about 1–4% have a primary (first) CMV infection during pregnancy. About one-third

of these infections are transmitted to the fetus, either by crossing the placenta or perinatally. Most infants with congenital CMV have no problems. However, infection in early pregnancy can cause miscarriage or birth defects, and CMV is a leading cause of congenital deafness. In later pregnancy, CMV infection may cause preterm labor, **stillbirth**, or serious newborn illness or death.

In the United States, about 30,000 children are born each year with congenital CMV infections, although 80% of them have no symptoms or problems. However, more than 5,000 have permanently disabling or potentially fatal CMV-related birth defects.

Other viral respiratory infections

Fifth disease, caused by parvovirus B19, is very common among children. About one-half of all adults are susceptible, and about one-third of infants whose mothers contract fifth disease during pregnancy show signs of infection at birth. Although not usually dangerous, fifth disease contracted early in pregnancy can cause miscarriage or severe fetal anemia (low red blood cells) that can lead to **congestive heart failure**.

A vertical infection with the *Varicella zoster* virus that causes **chickenpox** can lead to limb deformities early in development. If the mother contracts varicella during the first 20 weeks of pregnancy, there is a 2% risk of her child being born with varicella syndrome. However, the greatest risk results from a mother contracting varicella just before delivery, when she has not yet produced antibodies to protect her newborn.

In the past, **rubella** was a common cause of birth defects. Routine vaccinations have made vertical infections rare in the developed world. Rubella infection during the first 10 weeks of pregnancy may cause fetal death, and more than 50% of newborns have severe birth defects. Infections contracted later in pregnancy do not cause congenital defects, although the newborn may become seriously ill and eventually develop **diabetes mellitus**.

Bacterial infections

Maternal infection with group B streptococcus (GBS) at conception or within the first two weeks of pregnancy may lead to hearing and vision loss and mental retardation in the infant. Invasive GBS disease is also the most common cause of life-threatening infections in newborns. Up to 20% of pregnant women carry GBS in their vaginas during the last trimester, with the potential of infecting the infant during birth. Although premature infants are more susceptible to GBS, 75% of infected infants are born at full term. GBS is the most common cause of newborn **sepsis** (blood infection) and **meningitis** (infection of the fluid and membranes surrounding the brain and spinal cord). GBS also is a frequent cause of newborn **pneumonia**.

The foodborne bacterial infections listeriosis—caused by *Listeria monocytogenes*—and salmonellosis—caused by *Salmonella* bacteria—can be vertically transmitted. *L. monocytogenes* is ubiquitous in soil and groundwater, on plants, and in animals. Hormonal changes make pregnant women about 20 times more likely than other healthy adults to contract **listeriosis**, and about one-third of all cases occur in pregnant women. Listeriosis can cause miscarriage, fetal or newborn death, premature delivery, or severe illness in mother and infant.

Sexually transmitted infections (STIs)

Each year an estimated 8,000 pregnant women in the United States are infected with **syphilis** caused by the spirochete bacterium *Treponema pallidum*. Rising rates of syphilis among pregnant women are leading to increasing numbers of infants born with congenital syphilis—a severe, disabling, and often life-threatening disease that can cause facial deformity, blindness, and deafness.

Every year an estimated 40,000 pregnant women in the United States are infected with gonorrhea—caused by the bacterium *Neisseria gonorrhoeae*—and an estimated 200,000 are infected with chlamydia—caused by the bacterium *Chlamydia trachomatis*. Chlamydia can cause premature membrane rupture and labor. Both infections can cause newborn conjunctivitis—an inflammation of the eye.

Each year an estimated 8,000 pregnant women in the United States are infected with HIV, the human **immunodeficiency** virus that causes acquired immune deficiency syndrome (**AIDS**). Vertical infection during pregnancy, **childbirth**, or breastfeeding accounts for more than 90% of all childhood cases of HIV/AIDS.

Genital herpes is caused by herpes simplex virus (HSV) type-2 and, less frequently, by HSV type-1 that usually causes **cold sores**. About 25% of American adults are infected with HSV-2. There is little risk of vertical transmission if the mother is infected before the third trimester and has no genital sores at the time of delivery. Infection during the third trimester—when the virus is likely to be active and the mother has not yet made sufficient antibodies to protect her baby—can lead to congenital HSV infection. This can seriously damage the newborn's eyes, central nervous

WWW.BOOKBAZ.IR

system, and internal organs and lead to mental retardation and, rarely, death.

Genital or venereal **warts** are caused by some types of **human papillomavirus** (HPV). At least 20 million Americans are infected, and about 5.5 million new cases are reported annually. **Genital warts** are highly infectious, tend to grow faster during pregnancy, and can be vertically transmitted during birth.

An estimated 8,000 pregnant women are infected with **hepatitis B** virus (HBV) in the United States every year. They are at risk for premature delivery and, if untreated, newborns may develop chronic **liver disease**. Perinatal vertical transmission of HBV is very common in Asia. There is also a 4% risk of vertical transmission of the **hepatitis C** virus, depending on the mother's viral load and whether she is co-infected with HIV.

Causes and symptoms

Toxoplasmosis

The single-celled protozoan *T. gondii* produces its eggs in cat intestines. The eggs shed in cat feces and can survive for up to 18 months in the soil. Human infection occurs from handling contaminated soil or feces or by ingesting raw or undercooked meat from infected animals.

Although symptoms of toxoplasmosis usually are very mild or absent, vertical infection early in fetal development can cause:

- premature birth and low birth weight—under 5 lb (2.3 kg)
- slow growth
- fever
- skin rashes
- easy bruising
- anemia
- a small or large head (microcephaly or macrocephaly)
- fluid in the cavities of the brain (hydrocephaly)
- inflammation of the brain, heart, or lungs
- severe or prolonged jaundice
- enlarged liver and spleen
- an eye inflammation called choriorectinitis, which can lead to blindness
- severe illness or death shortly after birth

Symptoms of congenital toxoplasmosis may appear months or years after birth and include seizures or other neurological problems, **visual impairment**, **hearing loss**, or mental retardation.

CMV

Although most CMV-infected newborns have no symptoms, 10–15% may exhibit:

- low birth weight
- rashes
- small bruises
- jaundice
- enlarged liver and spleen
- hernias in the groin
- microcephaly or hydrocephaly
- respiratory problems
- developmental disabilities
- seizures

Although permanent disabilities are more likely if CMV symptoms are present at birth, 0.5–15% of CMV-infected infants develop hearing, vision, or neurological problems over several years.

Other viral respiratory infections

Symptoms of congenital fifth disease include:

- bright red rash on the cheeks
- lacy, red rash on the neck, trunk, and legs
- joint pain
- fatigue
- malaise

Varicella syndrome in a newborn is characterized by abnormally small limbs and head, scarring of the skin, eye defects, and mental retardation.

In addition to various birth defects, newborns infected with rubella early in the pregnancy may have:

- low birth weight
- bruising
- bluish-red skin lesions
- enlarged lymph nodes
- enlarged liver and spleen
- brain inflammation
- pneumonia

Bacterial infections

Although most GBS carriers have no symptoms, GBS in pregnant women may cause bladder or urinary tract infections, infection of the womb, or stillbirth. Vertical transmission is more likely if the mother:

- previously delivered a GBS-infected baby
- has a urinary tract infection caused by GBS
- carries GBS late in pregnancy
- begins labor or membrane rupture before 37 weeks of gestation
- has membrane rupture 18 hours or more before delivery
- experiences fever during labor

Symptoms of congenital GBS infection include breathing difficulties, **shock**, sepsis, pneumonia, and meningitis.

Listeriosis may cause flu-like symptoms, but it can be transmitted prenatally even if the mother has no symptoms. Symptoms of salmonellosis can be severe in pregnant women and newborns and may include **diarrhea**, **fever**, abdominal cramps, and, rarely, meningitis.

Syphilis

Syphilis can be vertically transmitted either prenatally or perinatally if the mother is infected during pregnancy or was inadequately treated for a past infection. Syphilis in adults usually causes genital lesions 10–90 days after exposure, with a rash developing six weeks later; however, symptoms may go unnoticed. Congenital syphilis can cause premature birth or stillbirth. A surviving newborn with untreated congenital syphilis may have no initial symptoms but may gain little weight (**failure to thrive**) and, during the first month of life, develop:

- rash or small fluid-filled blisters on the palms and soles of the feet
- rash and lesions around the mouth, genitalia, and anus
- fever
- severe congenital pneumonia
- enlarged lymph nodes, liver, and spleen
- bone inflammation and lesions
- nose cartilage infection or saddle nose (lacking a bridge)
- rarely, meningitis

Symptoms of late-stage congenital syphilis include:

- copper-colored rashes on the face, palms, and soles
- scarring around earlier lesions
- gray patches on the anus or outer vagina
- notched or peg-shaped teeth
- joint swelling
- bone pain
- abnormalities in the lower leg bones
- neurological conditions
- vision loss or blindness
- hearing loss or deafness

Gonorrhea and chlamydia

Symptoms of **gonorrhea** in women, if present, may include:

- bleeding during vaginal intercourse
- pain or burning with urination
- yellow or bloody vaginal discharge
- pelvic inflammatory disease

Both gonorrhea and chlamydia can be transmitted perinatally. **Conjunctivitis** caused by gonorrhea usually appears two to seven days after birth. Conjunctivitis caused by chlamydia usually appears five to 12 days after birth, although sometimes it takes six weeks to develop.

Viral STIs

HIV can be transmitted through the placenta or breast milk, but the risk is greatest during labor and delivery. The risk of HIV transmission is increased by a mother's use of illicit drugs, a high viral load (the amount of HIV in the mother's blood), severe inflammation of the fetal membranes, or a prolonged period between membrane rupture and delivery. HIV-infected infants do not have symptoms at birth, although about 15% develop serious symptoms or die within the first year. Almost half die by the age of 10.

Most women carrying HSV never have recognizable symptoms; however a first episode of genital herpes during pregnancy can be vertically transmitted and may cause premature birth. Both HSV-1 and HSV-2 can be transmitted during birth if the mother has active genital sores, causing facial or genital herpes in the newborn. Initial symptoms of congenital herpes usually appear within four weeks of birth and may be quite mild:

- blisters on the skin
- fever
- tiredness
- loss of appetite

More serious symptoms of congenital HSV infection include:

- skin rash with small fluid-filled blisters
- chronic or recurring eye and skin infections
- cataracts

WWW.BOOKBAZ.IR

KEY TERMS

Antibody—A blood protein produced in response to a specific foreign substance, such as a bacterium, virus, and parasite; the antibody destroys the organism, providing protection against disease.

Cesarean delivery—C-section; infant delivery through an incision in the abdominal and uterine walls.

Chlamydia—The most common sexually transmitted bacterial disease in the United States, caused by a rickettsia called *Chlamydia trachomatis*; it often occurs along with gonorrhea, and most infected women have no symptoms.

Conjunctivitis—An inflammation of the eye that can be caused by gonorrhea or chlamydia.

Cytomegalovirus (CMV)—A common human herpes virus that is normally not harmful but may cause severe complications if transmitted to a fetus.

Fifth disease—Erythema infectiosum; a common respiratory infection among children caused by parvovirus B19 that usually is not serious but can cause fetal complications.

Gonorrhea—A common sexually transmitted infection caused by the bacterium *Neisseria gonorrhoeae* that can be vertically transmitted.

Group B streptococcal (GBS) disease—A common bacterial infection that is potentially life-threatening if transmitted to a fetus during early pregnancy or delivery.

Hepatitis B and C—Viruses that can damage the liver and may be vertically transmitted during childbirth.

Herpes simplex virus (HSV)—A very common sexually transmitted infection; type-2 HSV causes genital herpes, and type-1 HSV usually causes cold sores but can cause genital herpes; HSV can be vertically transmitted during birth if the mother has an active infection.

HIV/AIDS—Human immunodeficiency virus/acquired immune deficiency syndrome; a sexually transmitted viral disease that can be vertically transmitted during pregnancy, childbirth, or breastfeeding.

Human papillomavirus (HPV)—A large family of viruses, some of which cause genital warts; HPV can be vertically transmitted during delivery.

Immune globulin—Serum containing antibodies against a specific infection.

- widespread infection affecting many organs including the lungs and liver
- a life-threatening brain infection called herpes encephalitis

Nearly 50% of women infected with HPV have no symptoms, but genital warts may appear weeks or months after infection. They can become larger during pregnancy, causing difficulty with urination. Vaginal warts can reduce the elasticity of the vagina and cause obstruction during delivery. Symptoms of congenital HPV infection may include lung infection and obstructed air passages from warts inside the windpipe.

Hepatitis B and C can be transmitted through the placenta, but are most often transmitted perinatally. Since the virus is thought to pass through the umbilical cord, a cesarean delivery does not prevent transmission. Approximately 90% of acute hepatitis B infections and up to 20% of chronic infections are vertically transmitted. Hepatitis viruses are not transmitted through breastfeeding. Congenital hepatitis B can cause chronic liver infection or even death, but typically symptoms are not apparent until young adulthood. Children infected at birth have a 25% risk of dying from **cirrhosis** or **liver cancer** as adults.

Diagnosis

Diagnosis of vertical infections can be difficult. An obstetrician may diagnose a maternal infection based on the woman's symptoms and blood tests. Sometimes a fetal infection can be diagnosed using **ultrasound**. Diagnosis of congenital infections in newborns may be based on a **physical examination**, symptoms, and blood or urine tests. Ultrasound scanning may be used to image the newborn's brain, and **echocardiography** may be used to diagnose heart problems.

Toxoplasmosis

Prenatal diagnosis of toxoplasmosis may be made with a blood test for maternal antibodies, testing of the amniotic fluid and fetal blood, or fetal ultrasound. Postnatal diagnosis of congenital toxoplasmosis involves antibody tests of the cord blood and cerebrospinal fluid, ophthalmologic and neurologic examinations, and computed axial tomography (CT or CAT) scans.

Listeriosis—A foodborne bacterial infection caused by *Listeria monocytogenes*; pregnant women are particularly susceptible and can transmit the disease to their fetuses.

Meningitis—An inflammation of the membranes covering the brain and spinal cord that can be caused by various congenital infections.

Perinatal—After membrane rupture or during labor or delivery.

Placenta—The uterine organ that provides nourishment to the fetus.

Prenatal infection—A maternal infection that is vertically transmitted to the fetus through the placenta.

Rubella—German measles; a viral infection that causes death or severe birth defects if vertically transmitted to the fetus during the first ten weeks of gestation.

Salmonellosis—Food poisoning; an infection by bacteria of the genus *Salmonella* that usually causes severe diarrhea and may be transmitted to a fetus.

Sepsis—Blood poisoning; a systemic or body-wide infection.

Sexually transmitted infection (STI)—An infectious disease that is transmitted through sexual activity.

Syphilis—A sexually and vertically transmitted infection with the spirochete bacterium *Treponema pallidum*.

Toxoplasmosis—Disease caused by the parasite *Toxoplasma gondii* that can cause severe damage if vertically transmitted.

Ultrasound—High-frequency sound waves that are used to visualize parts of the body or a fetus in the womb.

Varicella—Chickenpox; a disease caused by the *Varicella zoster* virus—human herpes virus 3—that can cause severe birth defects if vertically transmitted during the first 20 weeks of pregnancy and newborn complications if transmitted perinatally.

Viral load—The number of copies of a virus in one milliliter of blood; used to measure the severity of HIV and other viral infections.

Viral and bacterial infections

Blood tests can be used to diagnose listeriosis and to check for maternal antibodies against CMV or fifth disease. Ultrasound may be used to diagnose fetal fifth disease. GBS is diagnosed using bacterial cultures from blood, spinal fluid, skin, the vagina, or the rectum.

STIs

Infants are tested for syphilis at birth. Syphilis in an older infant may be diagnosed by a blood test, a **lumbar puncture** to look for signs of syphilis in the central nervous system, an ophthalmologic examination, dark-field microscopy to visualize the spirochete, or bone x rays.

Maternal gonorrhea can be diagnosed by staining or culturing a cervical smear or testing for the bacterial DNA in a urine or cervical sample.

Women who were not screened for HIV during pregnancy may be screened during labor or delivery with a rapid test. Although a negative HIV test at booking does not preclude neonatal infection—maternal infection and seroconversion can occur at any time during pregnancy and **lactation**. The most common screening for **HIV tests** for antibodies in the blood; however, most infants born to infected mothers test positive for six to 18 months because of the presence of maternal antibodies in their blood. A blood test for the presence of the virus detects only about 40% of newborn infections, so testing is repeated at one and six months.

An HSV culture from an affected genital site—preferably on the first day of the outbreak—can detect herpes simplex. A blood test can show if a woman has ever been infected with HSV and may distinguish between HSV-1 and HSV-2 and old or recently acquired infections. An examination or test can indicate whether a pregnant woman has active genital herpes near the time of delivery.

Genital warts are diagnosed visually. Vinegar may whiten infected areas to make them more visible. Cervical warts can be diagnosed by removing a piece of tissue for microscopic examination.

Treatment

Infants born with serious infections are treated in the **neonatal care** unit with intravenous drugs. Infants

WWW.BOOKBAZ.IR

born to infected mothers may be treated with medications even if they show few or no signs of infection.

Toxoplasmosis

Maternal toxoplasmosis is treated with spiramycin during the first and early second trimesters of pregnancy. Fetal toxoplasmosis may be treated by giving the mother pyrimethamine and **sulfonamides** such as sulfadiazine during the later second and third trimesters.

Newborns with symptoms of toxoplasmosis are treated with:

- pyrimethamine and sulfadiazine for one year
- leucovorin for one year to protect the bone marrow from pyrimethamine toxicity
- corticosteroids for heart, lung, or eye inflammation
- clindamycin
- a corticosteroid to reduce the inflammation of chorioretinitis

Viral respiratory infections

There is no effective treatment for CMV, although ganciclovir may be used to treat some symptoms.

Fetal anemia caused by fifth disease may resolve on its own. If the fetus is at risk for **heart failure**, a fetal blood **transfusion** may be necessary. The mother also may receive medication that passes through the placenta to the fetus.

Exposure to chickenpox or rubella by a nonimmune pregnant woman may be treated with an injection of immune globulin to help prevent fetal transmission. Congenital chickenpox is treated immediately to prevent serious complications or death. There is no specific treatment for fetal rubella infection.

Bacterial infections

Pregnant women with GBS in their urine are treated with penicillin. Most GBS carriers are treated with intravenous **antibiotics** from membrane rupture through labor to prevent fetal transmission. Infants born with congenital GBS infections are treated immediately with intravenous antibiotics. Maternal and congenital listeriosis and syphilis are also treated with antibiotics.

Maternal gonorrhea may be treated with cefixime, ceftriaxone, or levofloxacin. Since women often are infected with both gonorrhea and chlamydia, a combination of antibiotics, such as ceftriaxone and doxycycline or azithromycin, is used to treat both infections. Infants born to gonorrhea-infected mothers are treated with penicillin. Conjunctivitis caused by gonorrhea is treated with an eye ointment containing polymyxin and bacitracin, erythromycin, or tetracycline. An antibiotic such as ceftriaxone is given intravenously. Congenital chlamydia is treated with erythromycin eye ointment and oral tablets.

Viral STIs

Women who are being treated for HIV with combination drugs may stop treatment for the first trimester of pregnancy to avoid the risk of birth defects and to avoid missing doses due to **vomiting**, which can cause the growth of drug-resistant HIV strains. The side effects of **antiretroviral drugs** may worsen during pregnancy, but stopping treatment can worsen the woman's condition. HIV-positive pregnant women usually take zidovudine (ZDV) from 14 weeks of gestation on.

Pneumonia caused by *Pneumocystis carinii* is often the first AIDS-related illness in HIV-infected infants and is a major cause of death during the first year. The CDC recommends that all babies born to HIV-infected mothers be treated with anti-pneumonia drugs beginning at four to six weeks and continuing until the infant is shown to be HIV-negative.

Outbreaks of genital herpes just prior to delivery may be prevented by acyclovir, famciclovir, or valacyclovir. An HSV-infected newborn is treated immediately with intravenous **antiviral drugs** such as acyclovir. Eye infections are treated with trifluridine drops.

There is no cure for HPV, and treatment during pregnancy is often ineffective, although it may include:

- imiquimod cream
- 5% 5-fluorouracil cream
- trichloroacetic acid
- freezing or burning the warts with a laser
- surgical removal of warts
- alpha interferon injected into the wart

HPV infection in newborns is treated by surgically removing the warts. If warts obstruct breathing passages, frequent **laser surgery** is required. Interferon may be used to reduce the likelihood of recurrence.

Prognosis

Prognoses for vertical infections vary:

- The prognosis for congenital toxoplasmosis depends on its severity.

- Most infants with congenital CMV survive with treatment, but almost all suffer effects.
- Immediate penicillin treatment for GBS-infected newborns is very effective, although mortality is about 5%.
- Many fetuses infected with syphilis early in gestation are stillborn, and nearly 50% of untreated infants die shortly before or after birth. The risk to the baby is minimal if the mother is adequately treated with penicillin during pregnancy.
- HIV-positive pregnant women on combined antiretroviral therapy have a 1–2% risk of transmitting HIV to their fetuses. Congenital HIV infection that is treated with combination drugs, including protease inhibitors, may reduce the risk of death by 67%.
- Although immediate medication for HSV-infected newborns may prevent or reduce damage, half of infants born with widespread HSV infections die, and the other half may have brain damage.

Prevention

Prevention of vertical infection is central to avoiding congenital disease and disability. The CDC recommends that all pregnant women be screened on their first prenatal visit for syphilis, gonorrhea, chlamydia, HIV, and hepatitis B and C. General advice for preventing infection during pregnancy includes:

- good hygiene—including frequent, thorough hand washing and not sharing food or drinks—particularly for mothers who have or work with young children and may be at risk for CMV
- vaccinations several months before a planned pregnancy
- appropriate vaccinations after the first trimester of pregnancy
- contacting a healthcare provider immediately upon being exposed to a transmittable infection

Toxoplasmosis

It has been suggested that all pregnant women and newborns have blood screenings for toxoplasmosis. Maternal treatment with spiramycin within the first two weeks of pregnancy prevents transmission to the fetus. To avoid infection, pregnant women should:

- wash after handling cats, raw meat or poultry, soil, or sand
- avoid raw or undercooked meat and poultry, unwashed fruits and vegetables, raw eggs, and unpasteurized milk
- kill the parasite by freezing food or cooking it thoroughly
- keep cats indoors
- wear rubber gloves when handling cat litter and wash thoroughly afterward
- disinfect cat boxes with boiling water for five minutes
- cover sandboxes
- wear gloves for gardening and wash afterward
- avoid insects that may have been exposed to cat feces

Varicella and rubella

All non-immune women of childbearing age should be vaccinated against chickenpox and rubella before pregnancy. Pregnant women should be tested for immunity to rubella at their first prenatal visit.

Bacterial infections

About 25% of pregnant women have GBS in their rectum or vagina. They should be tested for GBS at 35–37 weeks of gestation to determine whether the bacteria are likely to be present at delivery. A GBS carrier's risk of delivering an infected child decreases from one in 200 to one in 4,000 if she is treated with intravenous antibiotics—usually penicillin—during labor. All women who have tested positive for GBS in their urine during pregnancy or who had a previous infant with GBS disease should be treated during labor. They cannot be treated before labor, because the bacteria return very quickly. Pregnant women who have not been tested at the onset of labor should receive antibiotics if:

- Labor begins at less than 37 weeks (preterm).
- Their water breaks 18 or more hours before delivery.
- They have a fever during labor.

Pregnant women should use precooked or ready-to-eat perishables as soon as they are opened, clean the refrigerator regularly, and keep the refrigerator at or below 40°F (4°C). However, since *Listeria* can grow at temperatures below 40°F (4°C), pregnant women should handle food cautiously and avoid:

- hot dogs and luncheon and deli meats unless they are reheated to steaming hot
- soft cheeses made from unpasteurized milk
- refrigerated meat spreads
- refrigerated smoked seafood unless it is well cooked
- raw (unpasteurized) milk

Salmonellosis may be prevented by:

- cooking all meat, poultry, seafood, and eggs thoroughly

WWW.BOOKBAZ.IR

- avoiding sushi containing raw fish
- washing raw vegetables thoroughly
- avoiding unpasteurized milk, soft cheeses, and alfalfa sprouts

STIs

STIs can be prevented by:

- abstaining from sexual contact outside of a mutually monogamous relationship with a noninfected partner
- using latex condoms correctly and consistently
- avoiding blood-contaminated needles, razors, or other items

An antibiotic ointment such as silver nitrate is applied under the eyelids of all newborns to prevent eye damage from gonorrhea.

Precautions for preventing fetal exposure to HIV-infected maternal blood include avoiding **amniocentesis**, fetal scalp blood sampling, and premature rupturing of the fetal membranes. Treatment with anti-HIV drugs during pregnancy and especially intravenous ZDV during labor and delivery, treating the infant after birth, and not breastfeeding in countries where there is an alternative reduce the risk of vertical HIV infection to almost zero. ZDV readily crosses the placenta and protects the baby from HIV infection during birth. At-risk newborns are given ZDV every six hours for six weeks. Mothers with a high viral load may have a scheduled cesarean delivery before labor begins and their waters break.

Prevention of vertical HSV transmission includes:

- abstaining from sexual activity during the last trimester of pregnancy or if there are signs of an outbreak or visible sores
- using a condom even if no symptoms are present
- postponing membrane rupture
- avoiding a fetal monitor that makes tiny punctures in the scalp
- avoiding vacuum or forceps deliveries that cause breaks in the infant's scalp
- having a cesarean delivery

Tenofovir is extremely effective in preventing *in utero* hepatitis B infection and, in combination with **vaccination**, may eradicate the disease altogether. Infants born to hepatitis B-infected mothers have a greater-than-95% chance of being protected against the virus if they receive the first dose of vaccine and hep B immune globulin (HBIG) within 12 hours of birth. The second and third doses of vaccine are given at one month and six months of age.

Vesicoureteral reflux

Definition

Vesicoureteral reflux (VUR) is a condition in which urine flows from the bladder, back up the ureter, and into the kidneys.

Demographics

VUR is most often diagnosed in children. No large studies have been done to determine the incidence of VUR. Small studies suggest that the condition occurs in less than 1% of healthy children, although some experts believe this is an underestimate. The condition is 10 times more common in white children than in African-American children and is especially common (for unknown reasons) in children with red hair.

Description

The normal flow of urine begins in the collecting system of each kidney. Urine then flows out of each kidney and into a tube called the ureter. Each ureter leads into the bladder where the urine collects until it is passed out of the body. Normally, urine should flow only in this direction. In vesicoureteral reflux, however, urine that has already collected in the bladder is able to flow backwards from the bladder, up the ureter, and back into the collecting system of the kidney. VUR may be present in either one or both ureters.

Vesicoureteral reflux causes damage to the kidneys in two ways. The kidney is not designed to withstand very much pressure. When VUR is present, backpressure of the urine on the kidney is significant. This can damage the kidney. In addition, the kidney usually is sterile, meaning that no bacteria are normally present within it. In VUR, bacteria that enter through the urinary tract may be carried back up the ureter with the urine. These bacteria can enter the kidney, causing severe infection.

Causes and symptoms

Most cases of VUR are due to a defect in the way the ureter is implanted into the bladder. The angle may be wrong, or the valve that should allow urine only one-way entrance into the bladder may be weak. Structural defects of the urinary system also may cause VUR. These include a situation in which two ureters leave a kidney, instead of the usual one (duplicated ureters), and in which the ureter is greatly enlarged at the end leading into the bladder (ureterocele).

VUR alone does not usually cause symptoms. Symptoms develop when an infection has set in. The usual symptoms of infection include frequent need to urinate, **pain** or burning with urination, and blood or pus in the urine. Occasionally, VUR is suspected when a child has a difficult time becoming toilet trained. In these cases, the bladder may become irritable and spasm because it is never totally empty of urine. When the kidneys have been damaged, high blood pressure may develop.

Diagnosis

VUR is most often diagnosed in infancy or childhood because of frequent urinary tract infections (UTIs).

Tests

VUR is diagnosed by taking a series of x-ray pictures (called a voiding cystourethrogram). These are taken after putting a small tube (catheter) into the bladder. The bladder is then filled with a dye solution that lights up on the x-ray picture. Pictures are taken immediately, followed by x rays taken while the patient is urinating. This will allow reflux to be demonstrated, and will reveal whether the level of reflux increases when pressure increases during

WWW.BOOKBAZ.IR

KEY TERMS

Bladder—The muscular sac which receives urine from the kidneys, stores it, and ultimately works to remove it from the body during urination.

Electrolyte—Salts and minerals that ionize in body fluids. The major human electrolytes are sodium (Na+), potassium (K+), calcium (Ca 2+), magnesium (Mg2+), chloride (Cl-), phosphate (HPO4 2-), bicarbonate (HCO3-), and sulfate (SO4 2-). Electrolytes control the fluid balance of the body and are important in muscle contraction, energy generation, and almost all major biochemical reactions in the body.

Reflux—A condition in which flow is backwards from normal.

Ureter—A muscular tube leading from the kidney to the bladder, down which the urine flows.

urination. Reflux is then graded based on the height and effects of the VUR:

- Grade I. VUR enters just the portion of the ureter closest to the bladder. The ureter appears normal in size.
- Grade II. VUR enters the entire ureter and goes up into the collecting system of the kidney. The ureter and the collecting system appear normal in size and structure.
- Grade III. VUR enters the entire ureter and kidney collecting system. Either the ureter or the collecting system are abnormal in size or shape.
- Grade IV. Similar to Grade III, but the ureter is greatly enlarged.
- Grade V. Similar to Grade IV, but the ureter is also abnormally twisted/curved, and the collecting system is greatly enlarged, with absence of the usual structural details.

Other tests that may be performed include a **urinalysis**, kidney and bladder **ultrasound**, intravenous pyelogram, or a nuclear scan of the kidney and bladder.

Treatment

Treatment depends on the grade of reflux that is diagnosed.

Drugs and monitoring

In grades I and II, the usual treatment involves long-term use of a small daily dose of **antibiotics** to prevent the development of infections. The urine is tested regularly to make sure that no infection occurs. The kidneys are evaluated regularly to make sure that they are growing normally and that no new scarring has occurred. Grade III VUR can be treated with antibiotics and careful monitoring. New infections, scarring, or stunting of kidney growth may result in a need for surgery. Grades IV and V are extremely likely to require surgery.

Surgery

Surgery for VUR consists of re-implanting the ureters into the bladder at a more normal angle. This usually improves the functioning of the valve leading into the bladder. When structural defects of the urinary system are present, surgery will almost always be required to repair these defects.

Prognosis

Prognosis is dependent on the grade of VUR. About 80% of children with grades I and II VUR simply grow out of the problem. As they grow, the ureter lengthens, changing its angle of entry into the bladder. About 50% of children with grade III VUR will require surgery. Nearly all children with grades IV and grade V VUR will require surgery. In these cases, it is usually best to perform surgery at a relatively young age in order to avoid damage and scarring to the kidneys.

Prevention

While there is no known method of preventing VUR, it is important to note that a high number of the siblings of children with VUR will also have VUR. Many of these siblings (about 36%) will have no symptoms, but will be discovered through routine examinations prompted by their brother's or sister's problems. It is important to identify these children, so that antibiotic treatment can be used to prevent the development of infection and kidney damage.

Vestibulitis *see* **Labyrinthitis**
Viagra *see* **Sildenafil citrate**
Vibrio cholera infection *see* **Cholera**
Vibrio parahemolyticus infection *see* **Vibriosis**

Vibriosis

Definition

Vibriosis is a disease caused by an infection with bacteria of the *Vibrio* genus, most commonly *Vibrio parahemolyticus* or *Vibrio vulnificus*. *Vibrio* bacteria cause **diarrhea**, skin infections, and/or blood infections. The diarrhea-causing *Vibrio parahemolyticus* is a relatively harmless infection, but *Vibrio vulnificus* infection, although rare, can lead to blood **poisoning** and death in many cases.

Description

Vibriosis is a general term referring to an infection by any member of the large group of *Vibrio* bacteria. The bacteria that causes **cholera** is in this group. Alternate names include non-cholera *Vibrio* infection, *Vibrio parahemolyticus* infection, and *Vibrio vulnificus* infection.

Vibrio parahemolyticus and *Vibrio vulnificus* are found in salt water. Infection with either of these two bacteria primarily occurs through eating contaminated raw seafood. Raw oysters are the usual source, although other seafood can carry the bacteria.

Vibrio parahemolyticus causes severe diarrhea. *Vibrio vulnificus* may cause diarrhea, but in persons with an underlying disease it may cause severe blood infections (septicemia or blood poisoning). Contact of a wound with seawater or contaminated seafood can lead to a *Vibrio vulnificus* skin infection.

Vibriosis is not very common in the United States. Most cases occur in coastal states between June and October. Between 1988 and 1991, there were only 21 reported cases of *Vibrio parahemolyticus* infection in the United States. Between 1988 and 1995, there were over 300 reports of *Vibrio vulnificus* infection in the United States.

Causes and symptoms

Vibriosis is caused by eating seafood contaminated with *Vibrio parahemolyticus* or *Vibrio vulnificus*. These bacteria damage the inner wall of the intestine, which causes diarrhea and related symptoms. *Vibrio vulnificus* can get through the intestinal wall and into the bloodstream.

Persons at risk for severe, often fatal vibriosis include those with **liver disease** (**cirrhosis**), excess iron (**hemochromatosis**), **thalassemia** (a blood disorder), **AIDS**, diabetes, or those who are immunosuppressed.

Symptoms of intestinal infection occur within two days of eating contaminated seafood. Symptoms last for 2 to 10 days and include watery diarrhea, abdominal cramps, nausea, **vomiting**, **headache**, and possibly **fever**. Symptoms of a blood infection develop one to two days after eating contaminated seafood, and include fever, chills, low blood pressure, and large fluid-filled blisters on the arms or legs. Similar blisters can also be produced by a *Vibrio vulnificus* skin infection.

Diagnosis

Vibriosis can be diagnosed and treated by an **infectious disease** specialist. It is diagnosed when *Vibrio* bacteria are grown from samples of stool, blood, or blister fluid. The symptoms and a recent history of eating raw seafood are very important clues for diagnosis.

Treatment

To counteract the fluid loss resulting from diarrhea, the patient will receive fluids either by mouth or intravenously. **Antibiotics** are not helpful in treating *Vibrio parahemolyticus* diarrhea.

However, *Vibrio vulnificus* infections are treated with antibiotics such as tetracycline (Sumycin, Achromycin V), or doxycycline (Monodox) plus ceftazidime

WWW.BOOKBAZ.IR

(Ceftaz, Fortraz, Tazicef). One out of five patients with vibriosis requires hospitalization.

Prognosis

Most healthy persons completely recover from diarrhea caused by *Vibrio* bacteria. *Vibrio vulnificus* blood infection affects persons with underlying illness and is fatal in half of those cases. *Vibrio vulnificus* wound infections are fatal in one quarter of the cases.

Prevention

Contamination with *Vibrio* bacteria does not change the look, smell, or taste of the seafood. Vibriosis can be prevented by avoiding raw or undercooked shellfish, keeping raw shellfish and its juices away from cooked foods, and avoiding contact of wounded skin with seawater or raw seafood.

Vision training

Definition

Vision training, also known as vision therapy or orthoptics, consists of a variety of programs to enhance visual performance. It includes treatments for focusing, binocularity, and eye movement problems. Vision training is generally provided by an optometrist (O.D.).

Purpose

While visual acuity refers to how clearly each eye can see, vision training addresses how well the two eyes work together as a team. When looking at an object, the eyes must focus on the object (e.g., focusing for near or far objects). This involves the lens system of the eyes. The eyes must also work as a team and point at the same object so that the person does not see double. Aiming precisely at the same object will aid in depth perception (stereopsis) and seeing objects in three-dimensions (3D).

Although crossed eyes (**strabismus**) is an obvious condition, many defects in the coordination of eye movement are far less apparent. Even so, they can cause problems in reading, driving vehicles, and other complex tasks that require the integrated function of eyes and body. It is the goal of vision therapy to improve these subtle interactions using carefully devised exercises and devices.

The discipline, called "behavioral optometry," involves a careful evaluation of visual function, concentrating on complex skills such as rapid reading, distance perception, peripheral field awareness, accommodative facility, and the coordinated movement of each eye in relationship to the other. From that assessment the doctor goes on to design a course of exercises to correct the problems discovered. Like any other type of training, success requires practice and persistence until habits and reflexes are retrained.

There are a number of different techniques and instruments used in vision therapy; the field is evolving rapidly in many directions. Some computerized exercises were being developed in the early 2000s that promised better patient motivation. A device called the Dynavision apparatus produced positive results in retraining **stroke** victims to operate motor vehicles. In addition, traditional forms of vision therapy have increased reading efficiency in an older age group (62–75 years).

Because the goal of vision training is to improve visual efficiency and visual processing, people having problems reading should consider a vision training evaluation. Children rubbing their eyes while reading, avoiding reading, or getting headaches while reading should be evaluated. Problems with sustaining focusing (accommodative insufficiency) or problems keeping words single (convergence or divergence problems) may be present. A full eye-health evaluation and vision training workup may reveal a problem. Vision training is also appropriate for people learning how to coordinate the eyes after surgery for strabismus. Vision training can also be used in lazy eye (**amblyopia**) and includes patching the eye and doing various exercises.

Dyslexia is a problem with following the flow of words when reading. Often the order of letters or words appear reversed. It is a complex problem involving the way the brain processes the stream of information coming in from the eyes. While vision therapy is not a

treatment for dyslexia or learning disabilities, there may be an underlying visual processing problem that may be present. Vision therapy can be part of a multidisciplinary approach to treating learning disabilities.

Sports vision deals with visual performance in sport-related activities. Protective eyewear is also a large consideration when participating in sports. Basketball, baseball, racquetball, and swimming (and other sports as well) can all cause injury to the eyes. Batting helmets with face shields, protective goggles with polycarbonate lenses, or something as simple as ultraviolet (UV) coatings on glasses to protect the eyes from the sun in outdoor sports such as golf can protect the eyes. Hitting a baseball or throwing a basketball into a hoop requires accurate fixation. Golfers need to see clearly and judge distance. Bifocals may need to be adjusted to allow for putting, driving, and reading the score card. While many of these issues (e.g., UV coatings) can be addressed at a regular eye exam, sports vision may be able to help with more specific, individual problems.

Precautions

Behavioral optometry is a relatively new field of study. Results are mixed. Newer techniques, more refined evaluation methods, and newer pieces of apparatus are continuously being appraised. More study results are needed to define the scope and benefits of this discipline.

Description

Vision therapy is individually tailored to the subject and the discovered problems. It can be a lengthy process with many variations that requires repetition until eye muscles, coordination, reflexes, habits, and the way the brain handles visual input are all retrained. Each program is individualized. The patient should be aware of the time involved for treatment. Treatment can be from several weeks to several months depending upon the condition. Some insurance plans may cover vision training.

Preparation

If vision therapy is recommended, the optometrist will discuss thoroughly what is expected and necessary for success. The patient must be prepared to perform some eye exercises at home.

Aftercare

Even after the treatment is successful, it may be necessary to continue the exercises to maintain the benefits. It may be necessary to repeat treatment in the future.

KEY TERMS

Accommodation—The focusing of the lens of the eye.

Binocular—Both eyes accurately pointing to the same object.

Stereopsis—The visual perception of depth or the ability to see three-dimensionally. For this to occur, the person must be binocular.

Risks

No risk is involved. The treatment is safe.

Results

A carefully and individually tailored program of vision therapy should result in a gradual improvement in whatever complex visual function is being addressed. This progress ought to be measurable by using the same tests that were used to diagnose it. If the patient had symptoms, such as headaches or double vision while reading, it should be alleviated.

Abnormal results

Because the treatment is safe, the only abnormal result is failure. At the start of treatment, the optometrist should provide a reasonable estimate of what improvement to expect and how long it will take. Should this prove incorrect, either the treatment needs to be modified or the problem deemed untreatable by that method.

WWW.BOOKBAZ.IR

Visual impairment

Definition

Total blindness is the inability to tell light from dark, or the total inability to see. Visual impairment or low vision is a severe reduction in vision that cannot be corrected with standard glasses or **contact lenses** and reduces a person's ability to function at certain or all tasks. Legal blindness (which is actually a severe visual impairment) refers to a best-corrected central vision of 20/200 or worse in the better eye or a visual acuity of better than 20/200 but with a visual field no greater than 20° (e.g., side vision that is so reduced that it appears as if the person is looking through a tunnel).

Description

Vision is normally measured using a Snellen chart. A Snellen chart has letters of different sizes that are read, one eye at a time, from a distance of 20 feet. People with normal vision are able to read the 20-foot line at 20 feet, which is 20/20 vision, or the 40-foot line at 40 feet, the 100-foot line at 100 ft, and so forth. If at 20 ft the smallest readable letter is larger, vision is designated as the distance from the chart over the size of the smallest letter that can be read.

Eye care professionals measure vision in many ways. Clarity (sharpness) of vision indicates how well a person's central visual status is. The diopter is the unit of measure for refractive errors such as nearsightedness, farsightedness, and **astigmatism** and indicates the strength of corrective lenses needed. People do not just see straight ahead; the entire area of vision is called the visual field. Some people have good vision (e.g., see clearly) but have areas of reduced or no vision (blind spots) in parts of their visual field. Others have good vision in the center but poor vision around the edges (peripheral visual field). People with very poor vision may be able only to count fingers at a given distance from their eyes. This distance becomes the measure of their ability to see.

The World Health Organization (WHO) defines impaired vision in five categories:

- Low vision 1 is a best corrected visual acuity of 20/70.
- Low vision 2 starts at 20/200.
- Blindness 3 is below 20/400.
- Blindness 4 is worse than 5/300
- Blindness 5 is no light perception at all.
- A visual field between 5° and 10° (compared with a normal visual field of about 120°) goes into category 3; less than 5° into category 4, even if the tiny spot of central vision is perfect.

Color blindness is the reduced ability to perceive certain colors, usually red and green. It is a hereditary defect and affects very few tasks. Contrast sensitivity describes the ability to distinguish one object from another. A person with reduced contrast sensitivity may have problems seeing things in the fog because of the decrease in contrast between the object and the fog.

According to the WHO there are over 40 million people worldwide whose vision is category 3 or worse, 80% of whom live in developing countries. Half of the blind population in the United States is over 65 years of age.

Causes and symptoms

The leading causes of blindness include:

- macular degeneration
- glaucoma
- cataracts
- diabetes mellitus

Other possible causes include infections, injury, or **nutrition**.

Infections

Most infectious eye diseases have been eliminated in the industrialized nations by sanitation, medication, and **public health** measures. Viral infections are the main exception to this statement. Some infections that may lead to visual impairment include:

- Herpes simplex keratitis. A viral infection of the cornea. Repeated occurrences may lead to corneal scarring.
- Trachoma. This disease is responsible for six to nine million cases of blindness around the world, of the third of a billion who have the disease. Trachoma is caused by an incomplete bacterium, *Chlamydia trachomatis*, that is easily treated with standard antibiotics. It is transmitted directly from eye to eye, mostly by flies. The chlamydia gradually destroy the cornea.
- Leprosy (Hansen's disease). This is another bacterial disease that has a high affinity for the eyes. It, too, can be effectively treated with medicines.
- River blindness. Much of the tropics of the Eastern Hemisphere are infested with *Onchocerca volvulus*, a worm that causes "river blindness." This worm is transmitted by fly bites and can be treated with a drug called ivermectin. Nevertheless, 28 million people have the disease, and 40% of them are blind from it.

Other causes

Exposure of a pregnant woman to certain diseases (e.g., **rubella** or **toxoplasmosis**) can cause congenital eye problems. Injuries to the eyes can result in blindness. Very little blindness is due to disease in the brain or the optic nerves. **Multiple sclerosis** and similar nervous system diseases, brain tumors, diseases of the eye sockets, and head injuries are rare causes of blindness.

Nutrition

Vitamin A deficiency is a widespread cause of corneal degeneration in children in developing nations. As many as five million children develop xerophthalmia from this deficiency each year. Five percent end up blind.

Diagnosis

A low vision exam is slightly different from a general exam. While a case history, visual status, and eye health evaluation are common to both exams, some things do differ. Eye charts other than a Snellen eye chart will be used. Testing distance will vary. A trial frame worn by the patient is usually used instead of the instrument containing the lenses the patient sits behind (phoropter). Because the low vision exam is slightly more goal oriented than a general exam, for example, what specifically is the patient having trouble with (reading, seeing street signs, etc.) different optical and nonoptical aids will generally be tried. Eye health is the last area to be checked so that the lights necessary to examine the eyes will not interfere with the rest of the testing.

Treatment

There are many options for patients with visual impairment. There are optical and nonoptical aids. Optical aids include:

- Telescopes. May be used to read street signs.
- Hand magnifiers. May be used to read labels on things at the store.
- Stand magnifiers. May be used to read.
- Prisms. May be used to move the image onto a healthy part of the retina in some eye diseases.
- Closed circuit television (CCTV). For large magnification (e.g., for reading).

Nonoptical aids can include large print books and magazines, check-writing guides, large print dials on the telephone, and more.

For those who are blind, there are enormous resources available to improve the quality of life. For the legally blind, financial assistance for help may be possible. Braille and audio books are increasingly available. Guide dogs provide well-trained eyes and independence. Orientation and mobility training is available. There are special schools for blind children and access to disability support through Social Security and private institutions.

KEY TERMS

Cornea—The clear dome-shaped structure that is part of the front of the eye. It lies in front of the colored part of the eye (iris).

Diabetic retinopathy—Retinal disease caused by the damage diabetes does to small blood vessels.

Phoropter—The instrument used to measure refractive status of the eyes. It contains many lenses which are then changed in front of the eyes while the patient is looking at an eye chart. This is when the doctor usually asks, "Which is better, one or two?"

Xerophthalmia—A drying of the cornea and conjunctiva.

Prognosis

The prognosis generally relates to the severity of the impairment and the ability of the aids to correct it. A good low vision exam is important to be aware of the latest low vision aids.

Prevention

Regular eye exams are important to detect silent eye problems (e.g., **glaucoma**). Left untreated, glaucoma can result in blindness.

Corneal infections can be treated with effective **antibiotics**. When a cornea has become opaque beyond recovery it must be transplanted. Good hygiene (e.g., washing hands frequently) to prevent infection, proper use of contact lenses, and not sharing makeup are just some ways to guard against corneal infections.

Cataracts should be removed when they interfere with a person's quality of life.

Primary prevention addresses the causes before they ever begin. Fly control can be accomplished by simple sanitation methods. Public health measures can reduce the incidence of many infectious diseases. Vitamin A supplementation (when appropriate) will eliminate

WWW.BOOKBAZ.IR

xerophthalmia completely. It is possible that protecting the eyes against ultraviolet (UV) light will reduce the incidence of cataracts, **macular degeneration**, and some other eye diseases. UV coatings can be placed on regular glasses, sunglasses, and ski goggles. Patients should ask their eye care professional about UV coatings. Protective goggles should also be worn in certain situations (e.g., certain jobs, sports, even mowing the lawn).

Secondary prevention addresses treating established diseases before they cause irreversible eye damage. Having general physical checkups can also detect systemic diseases such as diabetes or high blood pressure. Control of diabetes is very important in preserving sight.

Vitamin A

Definition

Vitamin A is a fat-soluble micronutrient that the body needs to remain healthy. Humans must obtain vitamin A or its precursors from plant and animal foods. Vitamin A is sometimes called retinol.

Vitamin A

Age	Recommended dietary allowance		Tolerable upper intake level	
Children 0–6 mos.	1,333 IU	400 µg	2,000 IU	600 µg
Children 7–12 mos.	1,667 IU	500 µg	2,000 IU	600 µg
Children 1–3 yrs.	1,000 IU	300 µg	2,000 IU	600 µg
Children 4–8 yrs.	1,333 IU	400 µg	3,000 IU	900 µg
Children 9–13 yrs.	2,000 IU	600 µg	5,667 IU	1,700 µg
Boys 14–18 yrs.	3,000 IU	900 µg	9,333 IU	2,800 µg
Girls 14–18 yrs.	2,333 IU	700 µg	9,333 IU	2,800 µg
Men 19≤ yrs.	3,000 IU	900 µg	10,000 IU	3,000 µg
Women 19≤ yrs.	2,333 IU	700 µg	10,000 IU	3,000 µg
Pregnant women 18≥ yrs.	2,500 IU	750 µg	9,333 IU	2,800 µg
Pregnant women 19≤ yrs.	2,567 IU	770 µg	10,000 IU	3,000 µg
Breastfeeding women 18≥ yrs.	4,000 IU	1,200 µg	9,333 IU	2,800 µg
Breastfeeding women 19≤ yrs.	4,333 IU	1,300 µg	10,000 IU	3,000 µg

Food	Vitamin A (retinol)
Turkey giblets, cooked, ½ cup	25,948 IU
Beef liver, cooked, 3 oz.	22,175 IU
Chicken liver, cooked, 1 liver	2,612 IU
Skim milk, vitamin A fortified, 1 cup	500 IU
Butter, 1 tbsp.	355 IU
Cheddar cheese, 1 oz.	284 IU
Egg, 1 large	270 IU
Whole-milk yogurt, 1 cup	225 IU

Food	Vitamin A (provitamin A carotenoid)
Sweet potato, 1 medium	28,058 IU
Pumpkin, canned, ½ cup	19,065 IU
Carrot, raw, unpeeled, 1 whole	12,028 IU
Spinach, frozen, cooked, ½ cup	11,458 IU
Kale, frozen, cooked, ½ cup	9,557 IU
Cantaloupe, 1 cup	5,411 IU
Red pepper, 1 cup	4,665 IU
Papaya, 1 whole	2,888 IU
Mango, 1 whole	2,240 IU
Tomato juice, 8 oz.	1,094 IU

Note: 12 mcg of beta-carotene (from provitamin A) equals 1 mcg of retinol.
1 IU equals 0.3 mcg retinol and 0.6 mcg beta-carotene.
IU = International unit
µg = microgram (mcg)

(Table by PreMediaGlobal. © Cengage Learning.)

Purpose

Vitamin A affects many different systems in the body. It is important for maintaining good vision, especially in the dark, and for a healthy immune system, growing strong bones, reproduction, and embryonic development. Vitamin A affects gene expression by helping to turn on and off specific genes during cell division and differentiation. Obtaining the correct amount of vitamin A—not too little and not too much—is essential. Vitamin A deficiency can adversely affect vision, damage the cells lining various parts of the body, and make people more susceptible to infection.

Description

Vitamin A was the first fat-soluble vitamin to be discovered. However, ancient Egyptian, Chinese, and Greek physicians all knew that eating liver could cure night blindness. In 1913, two groups of American scientists experimenting with animal feed almost simultaneously discovered an essential substance that was present in whole milk but absent from fat-free milk. They called it "fat-soluble factor A," later vitamin A.

Vitamin A is actually a family of compounds known as retinoids, so-named because vitamin A has the biological activity of retinol, which was first isolated from the retina of the eye. Retinols are the predominant form of vitamin A in the human body. The most active retinol is 11-*cis*-retinol, known as preformed vitamin A. It is obtained from animal foods and is sometimes called "true" vitamin A, because it can be used directly by the body without undergoing any chemical changes. Preformed vitamin A can also be converted into retinoic acid, which is involved in controlling gene expression, and into retinal, another active form.

Plant carotenoids are also forms of vitamin A. Beta-carotene or provitamin A from plant foods is converted to active retinol in the body. Some other carotenoids, especially alpha-carotene and beta-cryptoxanthin, also can be converted into retinol by the body, although beta-carotene is converted twice as efficiently.

Vitamin A's role in health

The first function of vitamin A to be well understood was its role in vision, elucidated by Harvard scientist George Wald (1906–1997). Wald was awarded the Nobel Prize in 1967 for his work demonstrating that retinol was part of the light-absorbing pigment rhodopsin in the retina of the eye. Without enough vitamin A, the eye cannot detect low levels of light, and people with retinol deficiency develop night blindness. Night blindness disappears almost immediately when vitamin A is added to the diet. If left untreated, however, dry eye and permanent blindness can occur because of damage to the cornea, the clear covering of the eye.

Vitamin A has other important functions. It is an antioxidant that can help protect cells from the effects of free radicals that are both produced during normal metabolism and enter the body through environmental exposures such as tobacco smoke and radiation. Vitamin A is also important for the health of skin and other epithelial cells. Severe **acne** is sometimes treated with synthetic Vitamin A, and vitamin A supplements are often used to help burn victims grow new skin. Epithelial cells also line the throat, lungs, intestines, bladder, and other internal cavities that are the first line of defense against invading microorganisms. These cells require vitamin A to grow normally and form a continuous barrier against invasive bacteria and viruses. In addition, vitamin A is needed for the proper development of white blood cells that fight infection. Nevertheless, excess vitamin A does not appear to benefit the immune system. It remains unclear whether Vitamin A may help prevent or treat certain types of cancer.

Vitamin A requirements

The Institute of Medicine (IOM) of the U.S. National Academy of Sciences has developed dietary reference intake (DRI) values for **vitamins** and **minerals**. DRIs consist of three sets of values:

- The recommended dietary allowance (RDA) defines the average daily amount of the nutrient needed to meet the health needs of 97%–98% of the population.
- The adequate intake (AI) is an estimate set when there is not enough information to determine an RDA for a nutrient.
- The tolerable upper intake level (UL) is the average maximum amount of a nutrient that can be taken daily without risking negative side effects.

RDAs for vitamin A are measured in both micrograms (mcg) and international units (IU). IUs appear on dietary supplement labels. Because vitamin A has different forms with different activities and because vitamin supplements vary, not only in the amounts of vitamin A, but also in the forms of vitamin A, an equivalency measure called the retinol activity equivalent (RAE) allows different vitamin A sources to be compared. One RAE equals:

- 1 mcg of retinol
- 12 mcg of beta-carotene

WWW.BOOKBAZ.IR

- 24 mcg of other provitamin A carotenoids
- approximately 3 IU

Following are the daily AIs, RDAs, and ULs in RAE (mcg) and IUs of retinol for healthy individuals:

- infants 0–6 months: AI 400 RAE or 1,330 IU; UL 600 RAE or 2,000 IU
- babies 7–12 months: AI 500 RAE or 1,670 IU; UL 600 RAE or 2,000 IU
- children 1–3 years: RDA 300 RAE or 1,000 IU; UL 600 RAE or 2,000 IU
- children 4–8 years: RDA 400 RAE or 1,330 IU; UL 900 RAE or 3,000 IU
- children 9–13 years: RDA 600 RAE or 2,000 IU; UL 1,700 RAE or 5,610 IU
- males ages 14–18: RDA 900 RAE or 3,000 IU; UL 2,800 RAE or 9,200 IU
- females ages 14–18: RDA 700 RAE or 2,300 IU; UL 2,800 RAE or 9,200 IU
- males ages 19 and over: RDA 900 RAE or 3,000 IU; UL 3,000 RAE or 9,900 IU
- females ages 19 and over: RDA 700 RAE or 2,300 IU; UL 3,000 RAE or 9,900 IU
- pregnant girls ages 14–18: RDA 750 RAE or 2,500 IU; UL 2,800 RAE or 9,200 IU
- pregnant women ages 18 and over: RDA 770 RAE or 2,567 IU; UL 3000 RAE or 9,900 IU
- lactating girls ages 14–18: RDA 1,200 RAE or 4,000 IU; UL 2,800 RAE or 9,200 IU
- lactating women ages 18 and over: RDA 1,300 RAE or 4,300 IU; UL 3,000 RAE or 9,900 IU

Children who are ill may require more vitamin A. In particular, vitamin A significantly reduces the risk of complications from **measles**, especially eye damage and blindness, and lowers a child's risk of death from measles by 50%. The World Health Organization (WHO) recommends daily doses of 200,000 IU for two consecutive days for all children over 12 months of age with acute measles and lower doses for babies. A third dose two to four weeks later is recommended for children with clinical evidence of vitamin A deficiency.

Vitamin A from animal sources

Meat-eating Americans get about 70% of their dietary vitamin A from animal sources. Good sources of retinol include beef or chicken livers, whole eggs, whole milk, and cheese made with whole milk. Some processed foods, such as breakfast cereals and fat-free milk, are fortified with vitamin A in the form of retinol. About 80% of the dietary retinol is absorbed by the body. A portion of the vitamin A in supplements and multivitamins is usually in the form retinol.

Approximate vitamin A (retinol) contents for some common animal foods include:

- beef liver, 3 oz. (85 g) cooked, 27,185 IU
- chicken liver, 3 oz. (85 g) cooked, 12,325 IU
- butter, 1 tablespoon (15 mL), 325 IU
- whole milk, 1 cup (237 mL), 250 IU
- skim milk fortified with vitamin A, 1 cup (237 mL), 500 IU
- whole-milk cheddar cheese, 1 oz. (28 g), 280 IU
- egg, 1 whole, 300 IU

Vitamin A from plant sources

Carotenoids are the pigments in yellow and orange vegetables and in some deep-green vegetables in which the orange color is obscured. Good sources of beta-carotene include carrots, cantaloupe, apricots, mango, papaya, spinach, and kale. Vegans (who do not eat any animal products) must be especially careful to get enough of these vegetables.

Approximate provitamin A carotenoid contents of some common plant foods include:

- spinach, 1/2 cup frozen and boiled, 11,458 IU
- kale, 1/2 cup cooked, 9,560 IU
- carrot, 1 whole raw, 8,670 IU
- carrot, 1/2 cup raw, 1,285 IU
- cantaloupe, 1 cup, 5,410 IU
- papaya, 1 cup, 1,530 IU
- mango, 1 cup, 1,260 IU
- tomato juice, 6 oz. (177 mL), 820 IU
- breakfast cereal fortified with vitamin A, 1 serving, 500–770 IU

Precautions

Vitamin A excess

Excess vitamin A can be very harmful. Vitamin A is stored in the liver and, over time, excess vitamin A can build up to dangerous levels and cause liver damage. Too much vitamin A also activates the cells that break down bone (osteoclasts) and interferes with the activities of **vitamin D** that are involved in building and preserving bone. Studies have linked high levels of retinol in the blood with increased risk of hip fracture in people over age 50. Since **osteoporosis** (bone weakening) usually affects the elderly, some experts question the value of a daily vitamin A–containing multivitamin for people over age 55. Excess vitamin A can also disrupt menstrual cycles and cause chronic

KEY TERMS

Adequate intake (AI)—The daily average intake level of a nutrient that is likely to be adequate for a healthy, moderately active individual, as determined by the U.S. Institute of Medicine.

Antioxidant—Substances that prevent or reduce cellular damage from reactive oxygen species such as free radicals.

Beta-carotene—A carotenoid provitamin A in dark green and yellow fruits and vegetables that has one-twelfth the vitamin A activity of retinol.

Carotenoids—Various common red and yellow pigments, such as beta-carotene, some of which have vitamin A and antioxidant activity.

Dietary reference intake (DRI)—A system of nutritional recommendations used by the Institute of Medicine of the U.S. National Academy of Sciences and the U.S. Department of Agriculture.

Fat-soluble vitamin—A vitamin that dissolves in fat and can be stored in body fat or the liver.

Free radicals—Reactive atoms or groups of atoms that damage cells, proteins, and DNA.

International unit (IU)—An agreed-upon standard of physiological activity for a given biological substance such as a vitamin.

Micronutrient—A nutrient, such as a vitamin, that is required in minute amounts in the diet for growth and health.

Preformed vitamin A—Retinol and retinyl ester that are obtained from animal sources—fish, meat (especially liver) and dairy products—and that are used directly by the body or metabolized to retinal and retinoic acid.

Provitamin A—Carotenoids such as beta-carotene, alpha-carotene, and beta-cryptoxanthin that are converted to vitamin A in the body.

Recommended dietary allowance (RDA)—The approximate amount of a nutrient that should be ingested daily.

Retinal and retinoic acid—Active forms of vitamin A that are produced in the body from precursors in the diet.

Retinol—Preformed vitamin A that is obtained from animal sources in the diet; the form of vitamin A that is used as the standard for determining dietary intake.

Retinol activity equivalent (RAE)—The standard measure for vitamin A; 1 RAE is equal to 1 mcg of retinol, 12 mcg of beta-carotene, 24 mcg of other provitamin A carotenoids, or about 3 IU.

Tolerable upper intake level (UL)—The highest daily intake level of a nutrient that is unlikely to cause adverse health effects in almost all individuals in the general population, as determined by the U.S. Institute of Medicine.

feelings of illness, including **headache**, nausea, irritability, **fatigue**, and muscle and joint **pain**.

Excess vitamin A can cause **birth defects**. For this reason, certain prescription medications containing synthetic vitamin A should not be taken by pregnant women or women who could become pregnant.

Acute vitamin A excess usually occurs from taking large quantities of a dietary supplement. Symptoms of acute excess include nausea, **vomiting**, blurred vision, headache, drowsiness, and altered mental states. Chronic vitamin A excess occurs when vitamin A builds up gradually in the body. Symptoms include loss of appetite, dry skin, hair loss, **insomnia**, fatigue, irritability, **diarrhea**, menstrual irregularities, bone pain, and reduced growth rate in children.

Vitamin A deficiency (VAD)

Poor night vision, dry skin, dry hair, broken fingernails, and decreased resistance to infections are among the first signs of vitamin A deficiency. Almost all healthy people in most developed countries obtain adequate vitamin A in their normal **diets** to maintain health; however, certain people are at greater risk for vitamin A deficiency:

- the malnourished, elderly, or chronically ill
- strict vegans, especially children, who eat no animal products
- people with gastrointestinal diseases, such as Crohn's disease, celiac disease, or inflammatory bowel disease, that interfere with the absorption of nutrients from the intestines
- people with disorders of the pancreas that interfere with the absorption of nutrients
- people with anorexia nervosa (self-starvation), cystic fibrosis, or liver disease
- alcoholics

In stark contrast, VAD is a major problem in the developing world, especially in parts of Africa and

WWW.BOOKBAZ.IR

Southeast Asia where famine and limited food choices often prevent people—especially children—from obtaining enough vitamin A and other nutrients. WHO estimates that more than 124 million children worldwide have a vitamin A deficiency and that one to two million children between the ages of one and four die each year from VAD. VAD is also the most common cause of childhood blindness—at least 250,000 children go blind because of VAD each year. Children with VAD are also at higher risk of dying from measles, diarrhea, **malaria**, and other infections. In addition to vitamin A supplements for children in the developing world, scientists are breeding and genetically engineering varieties of crops, such as rice and cassava, with increased vitamin A contents.

Interactions

Vitamin A may interact with some medications and other substances:

- antacids, which may be more effective when used in combination with vitamin A
- birth control pills, which increase the level of vitamin A in the blood
- blood-thinning medicines such as warfarin (Coumadin), whose effect may be enhanced by long-term use of vitamin A
- cholesterol-lowering drugs, which may reduce the body's ability to absorb vitamin A
- orlistat, a weight-loss drug marketed as Xenical or Alli that prevents fat from being absorbed, and olestra, which replaces fats in some foods, may decrease the amount of vitamin A absorbed from the intestines
- alcohol
- zinc and iron

Complications

Vitamin A is safe when taken in amounts recommended by the IOM. Too much or too little vitamin A results in serious health problems.

The AIs, RDAs, and ULs for vitamin A are much lower for children than for adults. Accidental overdose can occur if children consume adult vitamins or dietary supplements.

Vitamin B_1 *see* **Beriberi**

Vitamin B_2 deficiency *see* **Riboflavin deficiency**

Vitamin B_6

Definition

Vitamin B_6 is a water-soluble B complex vitamin that is required by the body to remain healthy. Humans cannot make vitamin B_6, so they must get it from foods in their diet. Vitamin B_6 is also called pyridoxine.

Purpose

Vitamin B_6 is a coenzyme or cofactor, meaning that it functions in conjunction with many different enzymes and is necessary for more than 100 different enzyme reactions that are involved in human metabolism. Thus, vitamin B_6 has a broad range functions that affect many different bodily systems. It is involved in the metabolism of neurotransmitters that carry the impulses between nerves, and thus is essential for nervous system function. It is involved in the formation of new skin and other cells. It is involved in the conversion of stored carbohydrates into energy and helps keep blood sugar (glucose) within a normal range. Vitamin B_6 is required for producing hemoglobin that carries oxygen in red blood cells. It is important for breaking down proteins into amino acids, so that the more protein that is consumed, the higher the vitamin B_6 requirement. Vitamin B_6 is important for the functioning of the immune system, because it is involved in the production of antibodies for fighting disease. Vitamin B_6 is involved in brain development in the fetus and infant. It is important for the production of DNA, the genetic material of all cells, and, along with vitamin B_{12} and **folic acid** (vitamin B9), it helps regulate the levels of an amino acid in the blood called **homocysteine** that may be linked to **heart disease**.

Vitamin B_6

Age	Recommended dietary allowance (mg)	Tolerable upper intake level (mg)
Children 0–6 mos.	0.1 (AI)	Not established
Children 7–12 mos.	0.3 (AI)	Not established
Children 1–3 yrs.	0.5	30
Children 4–8 yrs.	0.6	40
Children 9–13 yrs.	1.0	60
Boys 14–18 yrs.	1.3	80
Girls 14–18 yrs.	1.2	80
Adults 19–50 yrs.	1.3	100
Men 51≤ yrs.	1.7	100
Women 51≤ yrs.	1.5	100
Pregnant women 18≥ yrs.	1.9	80
Pregnant women 19≤ yrs.	1.9	100
Breastfeeding women 18≥ yrs.	2.0	80
Breastfeeding women 19≤ yrs.	2.0	100

Food	Vitamin B_6 (mg)
Cereal, 100% fortified, ¾ cup	2.00 (avg.)
Chickpeas, canned, 1 cup	1.10
Yellowfin tuna, 3 oz.	0.88
White rice, enriched, 1 cup	0.83
Potato, baked, with skin	0.62
Pork chops, bone in, 3 oz.	0.60
Salmon, 3 oz.	0.59
Beef, sirloin, 3 oz.	0.53
Brussels sprouts, frozen, boiled, 1 cup	0.45
Banana	0.43
Sweet potato, baked, with skin	0.42
Trail mix, 1 cup	0.38
Lentils, boiled, 1 cup	0.35
Ground beef, 80/20, 3 oz.	0.31
Peanuts, 1 oz.	0.13

AI = Adequate intake
mg = milligram

SOURCE: U.S. Department of Agriculture, National Agricultural Library, Food and Nutrition Information Center and USDA Agricultural Research Service.

(Table by PreMediaGlobal. © Cengage Learning.)

B_6 is unique among **vitamins** in that either a deficiency or an excess can cause **peripheral neuropathy**, a condition of nerves outside of the central nervous system that is characterized by muscle weakness, numbness, and **pain**. Vitamin B_6 deficiency can also cause problems with the skin and the blood, including a type of anemia in which there are too few functioning red blood cells.

Description

Vitamin B_6 was discovered in the 1930s and is one of the best-studied of the vitamins. Few vitamins and **minerals** have such a broad and diverse range of activities in the body as vitamin B_6.

WWW.BOOKBAZ.IR

There are three different forms of vitamin B_6—pyridoxine, pyridoxal, pyridoxamine—and three derivatives of each of these. All forms of vitamin B_6 are converted in the body into the same active molecule, pyridoxal 5'-phosphate. Vitamin B is a water-soluble vitamin. Unlike the fat-soluble vitamins A, D, E, and K, it is not stored in the body but rather is excreted in urine.

Normal vitamin B_6 requirements

The Institute of Medicine (IOM) of the U.S. National Academy of Sciences has developed dietary reference intake (DRI) values for vitamins and minerals. DRIs consist of three sets of numbers. The recommended dietary allowance (RDA) defines the average daily amount of the nutrient needed to meet the health needs of 97%–98% of the population. The adequate intake (AI) is an estimate of the daily requirement when there is not enough information to determine an RDA. The tolerable upper intake level (UL) is the average maximum amount that can be taken daily without risking negative side effects. These amounts are in milligrams (mg) for vitamin B_6:

- children 0–6 months: AI 0.1 mg; UL not established
- children 7–12 months: AI 0.3 mg; UL not established
- children 1–3 years: RDA 0.5 mg; UL 30 mg
- children 4–8 years: RDA 0.6 mg; UL 40 mg
- children 9–13 years: RDA 1.0 mg; UL 60 mg
- males 14–18 years: RDA 1.3 mg; UL 80 mg
- males 19–50 years: RDA 1.3 mg; UL 100 mg
- males 51 years and older: RDA 1.7 mg; UL 100 mg
- females 14–18 years: RDA 1.2 mg; UL 80 mg
- females 19–50 years: RDA 1.3 mg; UL 100 mg
- females 51 years and older: RDA 1.5 mg; UL 100 mg
- pregnant girls aged 14–18 years: RDA 1.9 mg; UL 80 mg
- pregnant women 19 years and older: RDA 1.9 mg; UL 100 mg
- lactating girls aged 14–18 years: RDA 2.0 mg; UL 80 mg
- lactating women 19 years and older: RDA 2.0 mg; UL 100 mg

Sources of vitamin B_6

Vitamin B_6 is found in many foods including chicken, pork, liver, fish, nuts, milk, potatoes, dark green vegetables, dried beans, avocados, bananas, wheat germ, and whole grains. It may be added to fortified breakfast cereals, breads, flour, and other grains. However, heating and freezing foods reduces their vitamin B_6 content. As much as 60%–80% of the vitamin B_6 in vegetables is lost during canning, and about 40% of B_6 in fruit is lost by canning. Processing of meat and grains also reduces their vitamin B_6 content.

Approximate vitamin B_6 contents of some common foods include:

- potato, medium with skin, baked,: 0.70 mg
- banana, 1 medium: 0.68 mg
- chicken or turkey breast, 4 oz. (113 g) roasted: 0.64 mg
- salmon, 4 oz. (113 g) baked or broiled: 0.52 mg
- cod, 4 oz. (113 g) baked or broiled: 0.52 mg
- beef tenderloin, lean, 4 oz. (113 g): 0.49 mg
- halibut, 4 oz. (113 g) baked or broiled: 0.45 mg
- pork loin, lean, 3 oz. (85 g): 0.42 mg
- watermelon, 1 cup: 0.22 mg
- spinach, 1/2 cup fresh, cooked: 0.22 mg
- spinach, 1/2 cup frozen, cooked: 0.14 mg
- carrots, 1 cup raw: 0.18 mg
- tuna, 3 oz. (85 g) canned: 0.18 mg
- green peas, 1/2 cup: 0.17 mg
- peanut butter, smooth, 2 tablespoons: 0.15 mg
- breakfast cereal, fortified with 100% of the RDA, 3/4 cup: 2.0 mg
- breakfast cereal, fortified with 25% of the RDA, 3/4 cup: 0.5 mg

Role of vitamin B_6 in health

Enzymes are proteins that promote (catalyze) chemical reactions within the body. Coenzymes or cofactors are molecules that are required to join with enzymes for their activity. Some of the more than 100 enzyme reactions that require vitamin B_6 include:

- Producing neurotransmitters. Neurotransmitters are molecules that carry information from one nerve to the next. Vitamin B_6 is directly involved in the formation of the neurotransmitter serotonin in the brain and indirectly involved in the production of the neurotransmitters dopamine, epinephrine, norepinephrine, melatonin, and gamma-aminobutyric acid (GABA). Inadequate amounts of these neurotransmitters are associated with mood changes, such as depression, and poor functioning of the nervous system.
- Hemoglobin function. Hemoglobin is the molecule in red blood cells that carries oxygen throughout the body, and vitamin B_6 is required for producing efficient hemoglobin.

KEY TERMS

Adequate intake (AI)—The daily average intake level of a nutrient that is likely to be adequate for a healthy, moderately active individual, as determined by the U.S. Institute of Medicine.

Amino acids—The basic building blocks of proteins.

Anemia—A deficiency in red blood cells, in the hemoglobin component of red blood cells, or in total blood volume.

Coenzyme—Cofactor; a small molecule, such as vitamin B_6, that binds to an enzyme and catalyzes (stimulates) enzyme-mediated reactions.

Dietary supplement—A product, such as a vitamin, mineral, herb, amino acid, or enzyme, that is used in addition to one's diet with the expectation that it will maintain or improve health.

Enriched—Having some of the nutrients added back that were lost during processing.

Enzyme—A protein that promotes a chemical reaction within the body.

Folic acid—Folate; vitamin B_9.

Fortified—Having added nutrients, such as vitamin B_6, that do not occur naturally in that food.

Hemoglobin—A protein in red blood cells that binds oxygen in the lungs and delivers it to the cells of the body.

Homocysteine—An amino acid that is not usually present in protein and that is turned over with the aid of vitamin B_6; high blood levels of homocysteine have been associated with cardiovascular disease.

Neurotransmitter—A chemical that transmits signals between neurons or nerve cells.

Premenstrual syndrome (PMS)—An array of symptoms—including anxiety, irritability, depression, fatigue, insomnia, headache, and bloating—that affects some women prior to the onset of menstruation.

Pyridoxal 5'-phosphate—The active form of pyridoxine or vitamin B_6.

Recommended dietary allowance (RDA)—The approximate amount of a nutrient that should be ingested daily.

Tolerable upper intake level (UL)—The highest daily intake level of a nutrient that is unlikely to cause adverse health effects in almost all individuals in the general population, as determined by the U.S. Institute of Medicine.

Vitamin B_{12}—A water-soluble, cobalt-containing member of the complex of eight B vitamins that is required for many bodily functions, sometimes in conjunction with vitamin B_6 and folic acid.

Water-soluble vitamin—A vitamin that dissolves in water and is excreted in urine.

- Utilizing stored glycogen. Glycogen is the form in which sugar is stored in the liver and muscles. Vitamin B_6 is one of several B vitamins that is essential for breaking down glycogen to glucose (sugar) for energy during physical activity.
- Making nucleic acids. As cells divide to form new cells, the nucleic acids DNA and RNA must be produced, and this process requires vitamin B_6. Therefore, B_6 plays a role in cell division and wound healing.
- Turning genes on and off. Along with many other molecules, vitamin B_6 is involved in the activation and inactivation of various genes.
- Regulation of homocysteine. Increased levels of homocysteine, a non-protein amino acid, appear to be associated with increased damage to blood vessels and increased risk of heart disease. Vitamin B_6, along with folic acid and vitamin B_{12}, lowers the levels of homocysteine in the blood. However, large doses of B_6 do not appear to reduce the risk of heart disease.

Various health claims have been made for vitamin B_6. Vitamin B_6 is involved in the formation of dopamine, and adequate dopamine levels are known to reduce mood swings associated with **premenstrual syndrome** (PMS). Vitamin B_6 appears to reduce depression, irritability, headaches, bloating, and breast tenderness in some women. The American Congress of Obstetricians and Gynecologists has recommended that women take vitamin B_6 supplements under a doctor's supervision for **nausea and vomiting** during **pregnancy** (morning sickness). Vitamin B_6 is sometimes claimed to boost the immune system, decrease the likelihood of developing **kidney stones**, and improve mental functioning in the elderly. It has been used to treat **carpal tunnel syndrome**, depression, **attention deficit hyperactivity disorder (ADHD)** and **autism** in children, and drug-induced **movement disorders** in people with **schizophrenia**. None of these claims has been substantiated; however, many epidemiologic studies have shown a link between intake and/or blood levels of vitamin B_6 and a lower risk for colorectal cancer.

WWW.BOOKBAZ.IR

Vitamin B_6 deficiency

Vitamin B_6 deficiency is very rare in the United States, although it is associated with a few rare genetic disorders. Alcoholics are at higher risk for developing vitamin B_6 deficiency, as are the elderly and those who take certain medications or who have certain inflammatory disorders. People with kidney disorders or kidney transplants or with **autoimmune disorders** such as **rheumatoid arthritis**, **celiac disease**, Crohn's disease, ulcerative **colitis**, or inflammatory bowel disease sometimes develop vitamin B_6 deficiency. Internationally, **malnutrition**, lack of a varied diet, or a diet limited to non-enriched grains increases the risk of vitamin B deficiency.

Symptoms of vitamin B_6 deficiency develop slowing. They include skin and tongue sores and inflammation, scaly lips, or cracks at the corners of the mouth. Other symptoms include itchy **rashes** and anemia. Very low levels of vitamin B_6 can cause irritability, depression, confusion, and a weakened immune system. Infants with vitamin B_6 deficiency may become irritable or develop very sensitive hearing or seizures.

Precautions

The tolerable upper intake levels for vitamin B_6 are quite high—approximately 50 times the RDA, although there are no confirmed health benefits from large daily vitamin B_6 supplements. Even at high doses of vitamin B_6 supplements, few side effects have been reported, although these can include nausea, **vomiting**, and breast soreness. Very high doses (above 200 mg/day) over a long period can result in numbness in the arms and legs; burning, tingling, or pin-pricking of the hands and feet; problems with balance and coordination; and other sensory changes. These symptoms usually disappear within several months of stopping vitamin B_6 supplementation.

Parents should be aware that the RDA and UL for vitamins and minerals, including vitamin B_6, are much lower for children than for adults. Accidental overdose can occur if children take adult vitamins or dietary supplements.

Interactions

Vitamin B_6 reduces the effectiveness of tetracycline **antibiotics**, of the seizure drug phenytoin, and of levodopa used to treat Parkinson's disease. The **tuberculosis** drugs cycloserine (Seromycin) and isoniazid and penicillamine used to treat rheumatoid arthritis reduce the level of vitamin B_6 in the blood and may require B_6 supplementation on the advice of a physician. However, vitamin B_6 supplements may interact with cycloserine and worsen any seizures or nerve cell damage caused by the drug. Certain **epilepsy** drugs may both decrease vitamin B_6 levels, and vitamin B_6 may reduce the effectiveness of the drugs for controlling seizures. Theophylline, used to treat **asthma** and other lung diseases, can reduce vitamin B_6 levels and cause seizures.

Vitamin D

Definition

Vitamin D is necessary to human health. It is obtained from food and sunlight. Vitamin D is also known as vitamin D3 or cholecalciferol. The plant version is known as vitamin D2 or ergocalciferol. Both of these forms of vitamin D are used for supplements and food fortification. Vitamin D starts as 7-dehydrocholesterol, a precursor to the active form of vitamin D. When a person is in the sun, the ultraviolet rays from the sun pass through the skin, hit the precursor, and convert it to the previtamin D3 form. Once in this form, it will move into the interior of the body where over the next 36 hours it is converted into the active form of vitamin D.

Purpose

Although scientists are still working to understand the remarkable functions of vitamin D within the body, it is well known that the vitamin targets the intestine, the kidneys, and the bones. Vitamin D is also thought to play a role in brain, pancreas, skin, parathyroid, and reproductive health, and may also support the immune system in warding off diseases. The popularly known role of vitamin D is to regulate the amount of **calcium** circulating in the blood. Calcium is a mineral acquired through diet that is involved in building bones, muscle contraction, and nerve impulse transmission. Vitamin D helps regulate the absorption of calcium from the small intestine. Too little vitamin D can cause weak, brittle, deformed bones, known as **rickets** in children, or osteomalacia in adults.

Description

Vitamin D exists in several forms, two of which are important to humans. Vitamin D2, called ergocalciferol, is made by plants. Vitamin D2 can be manufactured synthetically by irradiating yeast. This type of vitamin D is most often found in dietary supplements and foods fortified with vitamin D. Vitamin D3, called cholecalciferol, is made naturally by the skin when it is exposed to ultraviolet rays in sunlight. Neither vitamin D2 nor D3 is active in the body. Both must be converted, first in the liver and then in the kidney, into an active form of vitamin D (1alpha, 25-dihydroxyvitamin D). Vitamin D in this entry refers to the active form of vitamin D.

Vitamin D's role in health

Although vitamin D has been known to play a role in bone health for many years, only recently have researchers begun to explore its effects on cell differentiation and on the immune system.

WWW.BOOKBAZ.IR

BONE HEALTH. The role of vitamin D and calcium are closely connected. The body needs calcium to build bones and teeth, contract muscles, transmit nerve impulses, and help blood to clot. Vitamin D helps the body get the calcium it needs by increasing the amount of calcium absorbed in the small intestine. Vitamin D is an active part of the feedback loop that maintains a normal level of calcium in the blood.

To maintain health, the amount of calcium in the blood must stay within a very narrow range. When the amount of calcium in the blood falls below normal, the drop is sensed by the parathyroid glands. The parathyroid glands are four separate clusters of specialized cells in the neck. Low blood calcium levels stimulate the parathyroid glands to secrete parathyroid hormone (PTH). PTH travels through the bloodstream and stimulates the kidney to increase the conversion of vitamin D2 and D3 into its active form. Active vitamin D is released into blood and stimulates the cells lining the small intestine to increase the amount of calcium that can be absorbed from digesting food. Vitamin D also causes the kidney to conserve calcium so that less is lost in urine. If these actions do not return the level of calcium in the blood to normal, vitamin D activates cells called osteoclasts that break down bone and return calcium from the bone to the bloodstream. People who do not have enough vitamin D absorb less calcium from the food they eat. To make up for this, calcium is taken from their bones, and the bones weaken and break more easily.

CANCER PREVENTION AND TREATMENT. Vitamin D also helps regulate cell differentiation. During development, cells divide over and over again. At some point, they are triggered to specialize (differentiate) into different types of cells—for example, skin, muscle, blood, or nerve cells. Vitamin D joins with other compounds to turn on and off more than 50 different genes that stop cell growth and start cell differentiation.

One characteristic of cancer cells is that they grow wildly, dividing many times more than normal cells without differentiating. Since vitamin D can stimulate cells to stop dividing and begin differentiating, researchers are investigating whether vitamin D can protect people from getting certain cancers, especially colon, prostate, skin, and **breast cancer**. The research has produced mixed results. Some studies found that vitamin D protected against **colon cancer**, while others found it offered no protection. The American Cancer Society (ACS) stated in its guidelines on **nutrition** and physical activity for cancer prevention that vitamin D may help protect against colorectal cancer but that there is not yet any evidence in support of its effects on other cancers. The ACS makes no recommendations on the amount of vitamin D needed to have a beneficial effect. Individuals interested in participating in clinical trials for vitamin D at no charge can find a list of open trials at http://www.clinicaltrials.gov.

OTHER DISORDERS. Vitamin D has been proven to successfully treat a few other disorders. **Psoriasis**, a skin disorder, often responds to ointments that contain synthetic vitamin D3 when other treatment options have failed. When the parathyroid glands fail to function or are removed during surgery, vitamin D supplements help to make up for the lack of PTH. Supplements are also used to treat rare inherited familial hypophosphatemia and Fanconi syndrome-related hypophosphatemia. Both of these are characterized by abnormally low levels of phosphate in the blood.

Normal vitamin D requirements

The United States Institute of Medicine (IOM) of the National Academy of Sciences has developed values called dietary reference intakes (DRIs) for **vitamins** and **minerals**. The DRIs consist of three sets of numbers. The recommended dietary allowance (RDA) defines the average daily amount of the nutrient needed to meet the health needs of 97%–98% of the population. The adequate intake (AI) is an estimate set when there is not enough information to determine an RDA. The tolerable upper intake level (UL) is the average maximum amount that can be taken daily without risking negative side effects.

RDA and UL levels are measured in both weight (micrograms or mcg) and international units (IU). The IU measurement is the measurement used on dietary supplement labels. For vitamin D, 1.0 mcg equals 40 IU.

The following are the RDAs and ULs for vitamin D for healthy individuals:

- infants 0–6 months: RDA 400 IU or 10 mcg per day; UL 1,000 IU or 25 mcg
- infants 7–12 months: RDA 400 IU or 10 mcg; UL 1,500 IU or 38 mcg
- children 1–3 years: RDA 600 IU or 15 mcg; UL 2,500 IU or 63 mcg
- children 4–8 years: RDA 600 IU or 15 mcg; UL 3,000 IU or 75 mcg
- children 9–70 years: RDA 600 IU or 15 mcg; UL 4,000 IU or 100 mcg
- adults older than 70: RDA 800 IU or 20 mcg; UL 4,000 IU or 100 mcg

- pregnant and breastfeeding women: RDA 600 IU or 15 mcg; UL 4,000 IU or 100 mcg

Exposing the face, arms, and legs to sunshine free of sunscreen for 15 minutes three or four times a week meets the dietary requirements for vitamin D for people with fair skin much of the time. It should be noted that sunshine through a window will not produce any vitamin D. However, people who live north of 40° latitude (approximately a line that extends from Philadelphia to San Francisco) may not get enough sun exposure to meet their dietary needs during winter months. Dark-skinned people may need to spend triple the amount of time in the sun as fair-skinned people to synthesize adequate amounts of vitamin D, since the increased amount of melanin pigment in dark skin slows vitamin D production. Using sunscreen with an SPF of 8 or higher also slows the production of vitamin D in the skin.

Vitamin D is not found in large amounts in many foods. However, since the 1930s, vitamin D has been added to about 99% of all milk and to some breakfast cereals, bread, orange juice, and infant formulas. In addition, the U.S. Food and Drug Administration requires all foods containing olestra, a compound that reduces fat absorption, to be fortified with the fat-soluble vitamins A, D, E, and K.

The following list gives the approximate vitamin D content for some common foods:

- cod liver oil, 1 tablespoon: 1,360 IU
- salmon, cooked, 3.5 ounces: 360 IU
- mackerel, cooked, 3.5 ounces: 345 IU
- tuna, canned in oil, 3 ounces: 200 IU
- milk, any type fortified, 1 cup: 100 IU
- orange juice, fortified, 1 cup: 100 IU
- cereal, fortified, 1 serving: 40 IU (average, serving sizes vary)
- egg, 1 whole: 20 IU

Precautions

Vitamin D deficiency

Vitamin D deficiency results in rickets in children and osteomalacia in adults. Rickets is a condition in which the bones do not harden because of a lack of calcium deposited in them. Instead they remain soft and become deformed. Osteomalacia is a weakening of bones in adults that occurs when they are broken down (demineralized) and calcium in the bones is returned to the blood. Vitamin D deficiency also can cause joint and muscle **pain**, and **muscle spasms**. Less severe cases can result in **osteoporosis** in older adults.

The vitamin D fortification program, along with the popularity of daily multivitamins, has greatly reduced the number of people in the United States who are vitamin D deficient. However, some groups remain at risk of vitamin D deficiency. These include:

- Infants who are exclusively breastfed. Breast milk provides only about 25 UL of vitamin D per quart (liter). The American Academy of Pediatrics recommends vitamin D supplements beginning no later than 2 months of age for babies who are only fed breast milk.
- Institutionalized or homebound people who rarely go outside. One study found that 60% of nursing home patients were vitamin D deficient.
- People living in northern latitudes who cover almost all their body for much of the year due to climate or religious requirements.
- People with gastrointestinal diseases, such as Crohn's disease, celiac disease, or inflammatory bowel disease, that interfere with the absorption of nutrients from the intestine.
- People with disorders of the pancreas that interfere with the absorption of nutrients.
- People with anorexia nervosa (self-starvation).
- People who have had part of their stomach or intestine surgically removed for weight loss or other reasons.

Vitamin D excess

Vitamin D excess in healthy individuals occurs only when large quantities of vitamin D are taken as a dietary supplement over several months. This can result in high calcium levels in the blood (**hypercalcemia**). Symptoms of vitamin D excess include nausea, **vomiting**, excessive thirst, weakness, and high blood pressure. Calcium deposits may develop in the kidneys, blood vessels, heart, and lungs. The kidneys may be permanently damaged and eventually fail completely.

Interactions

Research suggests that the following types of medications may increase the available amount of vitamin D in the body. People taking these drugs should not take a vitamin D supplement without consulting their healthcare provider:

- birth control pills
- hormone replacement therapy/estrogen replacement therapy
- isoniazid (INH) used to treat tuberculosis
- thiazide diuretics

WWW.BOOKBAZ.IR

KEY TERMS

Cell differentiation—The process by which stem cells develop into different types of specialized cells such as skin, heart, muscle, and blood cells.

Deficiency—Shortage of substances (as vitamins) necessary for health.

Fat-soluble vitamin—A vitamin that dissolves in and can be stored in body fat or the liver.

Fortified—Process of adding micronutrients (essential trace elements and vitamins) to food.

Hormone—A chemical messenger that is produced by one type of cell and travels through the bloodstream to change the metabolism of a different type of cell.

Mineral—An inorganic substance found in the earth that is necessary in small quantities for the body to maintain health. Examples include zinc, copper, and iron.

Osteoporosis—A condition found in older individuals in which bones decrease in density and become fragile and more likely to break. It can be caused by lack of vitamin D and/or calcium in the diet.

Steroid—A family of compounds that share a similar chemical structure. This family includes the hormones estrogen and testosterone, vitamin D, cholesterol, and the drugs cortisone and prednisone.

Vitamin—A nutrient that the body needs in small amounts to remain healthy but that the body cannot manufacture for itself and must acquire through diet.

Research suggests that the following types of medications may decrease the available amount of vitamin D in the body. People taking these drugs should discuss with their healthcare provider whether a vitamin D supplement is right for them:

- antacids taken daily for long periods
- calcium-channel blockers used to treat heart conditions and high blood pressure
- certain cholesterol-lowering medications that block fat absorption
- phenobarbital and similar anticonvulsants
- mineral oil taken on a daily basis
- orlistat, a weight loss drug marketed as Xenical or Alli

Complications

No complications are expected when vitamin D is used in the recommended amounts. Complications may result from insufficient or excess vitamin D.

Parents should be aware that the RDAs and ULs for vitamins and minerals are much lower for children than for adults. Accidental overdose may occur if children are given adult vitamins or dietary supplements.

Vitamin E

Definition

Vitamin E is a class of eight related fat-soluble organic compounds that the body needs to remain healthy. Humans cannot make vitamin E, so they must get it from foods in their diet. Alpha-tocopherol is the most biologically active form of vitamin E in humans, and vitamin E in dietary supplements is usually synthetic alpha-tocopherol.

Purpose

The primary role of vitamin E in the human body appears to be as an antioxidant. **Antioxidants** help protect the body against damage caused by free radicals. Free radicals are formed during normal metabolic processes. Free radicals in the body increase with exposure to environmental toxins such as cigarette smoke, ultraviolet light, and radiation. Free radicals react with and damage compounds in the body, especially DNA (the genetic material) and fats (lipids) in cell membranes. Cellular damage from free radicals plays an important role in **aging** and in the development of some diseases, such as cancer and cardiovascular disease. Antioxidants react with free radicals to neutralize them and prevent cellular damage. As a fat-soluble compound, vitamin E is an important lipophilic antioxidant that helps prevent damage to the lipids in cell membranes.

Description

The eight different but closely related compounds that comprise vitamin E are alpha-, beta-, gamma-, and delta-tocopherol and alpha-, beta-, gamma-, and delta-tocotrienol. Each of these compounds has a different degree of activity in the human body, with alpha-tocopherol as the most active form. Vitamin E in dietary supplements is usually a synthetic alpha-tocopherol called dl-alpha-tocopheryl acetate.

Vitamin E

Age	Recommended dietary allowance		Tolerable upper intake level	
Children 0–6 mos.	6.0 IU (AI)	4 mg (AI)	Not established	
Children 7–12 mos.	7.5 IU (AI)	5 mg (AI)	Not established	
Children 1–3 yrs.	9.0 IU	6 mg	300 IU	200 mg
Children 4–8 yrs.	10.5 IU	7 mg	450 IU	300 mg
Children 9–13 yrs.	16.5 IU	11 mg	900 IU	600 mg
Children 14–18 yrs.	22.5 IU	15 mg	1,200 IU	800 mg
Adult 19≤ yrs.	22.5 IU	15 mg	1,500 IU	1,000 mg
Pregnant women*	22.5 IU	15 mg	1,500 IU	1,000 mg
Breastfeeding women*	28.5 IU	19 mg	1,500 IU	1,000 mg

AI = Adequate intake
IU = International unit
mg = milligram
*Pregnant and breastfeeding women aged 19 or older. Amounts for women younger than 19 are equal to their age group.

(Table by PreMediaGlobal. © Cengage Learning.)

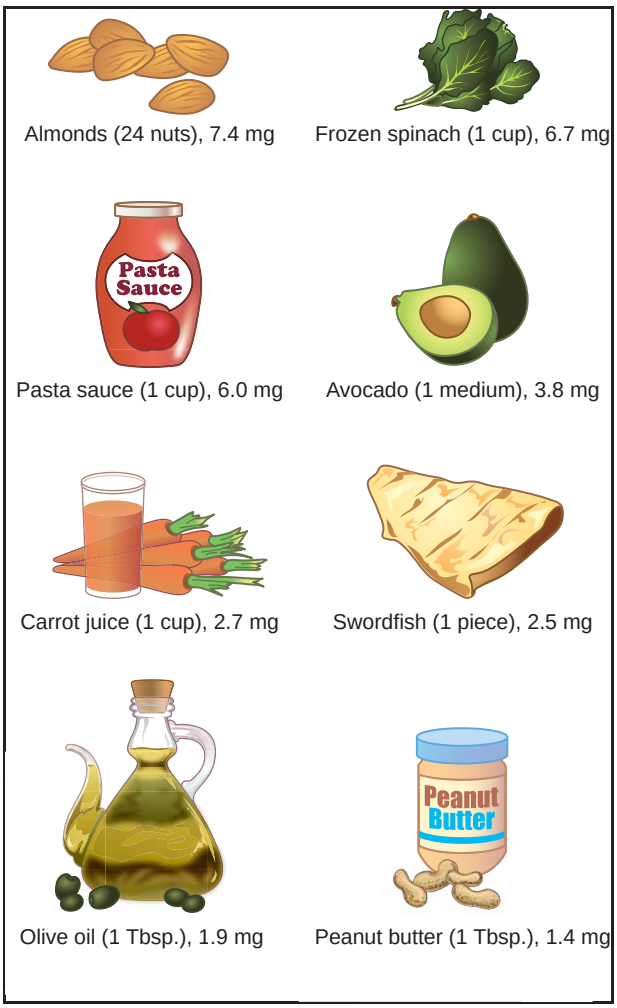
The functions of vitamin E in the human body are not well understood. Vitamin E first came to public attention in the 1980s, as scientists began to understand the importance of free-radical damage in the early development of atherosclerosis (artery clogging), as well as vision loss, cancer, and other chronic conditions.

Normal vitamin E requirements

The Institute of Medicine (IOM) of the U.S. National Academy of Sciences has developed dietary reference intake (DRI) values for **vitamins** and **minerals**. DRIs consist of three sets of numbers. The recommended dietary allowance (RDA) defines the average daily amount of a nutrient needed to meet the health needs of 97%–98% of the population. The adequate intake (AI) is an estimate set when there is not enough information to determine an RDA. The tolerable upper intake level (UL) is the average maximum amount that can be taken daily without risking negative side effects. The values are defined in both milligrams (mg) per day and the international units (IU) per day used on dietary supplement labels; 1 mg of alpha-tocopherol equals about 1.5 IU. There are different forms of alpha-tocopherol. The AIs and RDAs are defined for only the form of alpha-tocopherol that occurs naturally in foods and that is used in fortified foods and supplements, although other forms of alpha-tocopherol are also used in fortified foods and supplements. The ULs apply to any form of alpha-tocopherol:

- infants 0–6 months: AI, 6 IU or 4 mg; no defined UL
- infants 7–12 months: AI, 7.5 IU or 5 mg; no defined UL

WWW.BOOKBAZ.IR



(Table by PreMediaGlobal. © Cengage Learning.)

- children 1–3 years: RDA, 9 IU or 6 mg; UL, 300 IU or 200 mg
- children 4–8 years: RDA, 10.5 IU or 7 mg; UL, 450 IU or 300 mg
- children 9–13 years: RDA, 16.5 IU or 11 mg; UL, 900 IU or 600 mg
- children 14–18 years: RDA, 22.5 IU or 15 mg; UL, 1,200 IU or 800 mg
- adults ages 19 and older: RDA, 22.5 IU or 15 mg; UL, 1,500 IU or 1,000 mg
- pregnant females ages 14–18: RDA, 22.5 IU or 15 mg; UL, 1,200 IU or 800 mg
- pregnant females ages 19 and over: RDA, 22.5 IU or 15 mg; UL, 1,500 IU or 1,000 mg
- lactating females ages 14–18: RDA, 28.5 IU or 19 mg; UL, 1,200 IU or 800 mg
- lactating females ages 19 and over: RDA, 28.5 IU or 19 mg; UL 1,500 IU or 1,000 mg

Although the ULs have been challenged as being set too high, it is also believed that the vast majority of adults who do not take supplemental vitamin E are not getting the RDA for vitamin E. However, it is possible to obtain adequate vitamin E by consuming vitamin E–rich or–enriched foods.

Sources of vitamin E

A balanced diet that is low in fats and high in green, leafy vegetables and fiber from grains and cereals will usually provide an adequate amount of vitamin E. However, vitamin E is found in only a limited number of foods. In addition to green, leafy vegetables, some oils—especially safflower, sunflower, and cottonseed oils—and nuts have vitamin E. Meats, egg yolks, wheat germ, and whole-wheat products also have vitamin E. Some breakfast cereals are fortified with vitamin E, as indicated on the label. In addition, the U.S. Food and Drug Administration requires that all foods containing olestra, a compound that reduces fat absorption, be fortified with the fat-soluble vitamins A, D, E, and K. However, the bioavailability of vitamin E (amount that is absorbed by the body) varies in different foods.

The approximate vitamin E (alpha-tocopherol) content for some common foods includes:

- wheat germ oil, 1 tablespoon (15 mL): 30.5 IU or 20.3 mg
- sunflower oil, 1 tablespoon (15 mL): 8.5 IU or 5.6 mg
- safflower oil, 1 tablespoon (15 mL): 6 IU or 4.6 mg
- olive oil, 1 tablespoon (15 mL): 3 IU or 1.9 mg
- almonds, 1 oz. (28 g) roasted: 11 IU or 7.4 mg
- hazelnuts, 1 oz. (28 g) roasted: 6.5 IU or 4.3 mg
- peanuts, 1 oz. (28 g) roasted: 3 IU or 2.2 mg
- peanut butter, 1 oz. (28 g) fortified: 6 IU or 4.2 mg
- spinach, 1/2 cup raw: 3 IU or 1.8 mg
- spinach, 1/2 cup cooked: 2.5 IU or 1.6 mg
- avocado, 1 medium: 5 IU or 3.4 mg
- mango, 1/2 cup sliced: 1.5 IU or 1.0 mg
- kiwi, 1 medium: 1.5 IU or 1.0 mg

Multivitamins generally contain 30–60 IU or 20–40 mg of vitamin E. Vitamin E supplements typically contain 400–800 IU or 270–530 mg.

Vitamin E's role in health

Most of the health benefits that are claimed for vitamin E are based on its antioxidant properties. However, controversy surrounds the use of vitamin

E dietary supplements to help prevent or treat disease. Beginning as early as the 1940s, researchers suggested that vitamin E might protect against **heart disease**. Because vitamin E oxidizes LDL or "bad" **cholesterol**, researchers suggested that large doses might prevent or slow the build up of material on artery walls and thus help prevent cardiovascular disease. Initially it appeared that large doses of vitamin E might help prevent both heart disease and some cancers. Cardiologists began prescribing vitamin E supplements for their patients and taking the supplements themselves. When they began developing flu-like symptoms and realized they were experiencing toxic effects from the supplements, they cut back on the dose but continued taking vitamin E. Eventually, vitamin E studies began reporting mixed or contradictory effects. For example, a 2004 meta-analysis of 19 major clinical trials involving more than 136,000 individuals found that taking 400 IU or more of vitamin E daily increased the risk of death by about 4%. Other studies have indicated that high doses of vitamin E increase the risk of **heart failure**. The American Heart Association does not recommend the use of antioxidant supplements for preventing heart disease.

There are claims that vitamin E helps protect against cancer by strengthening the immune system and preventing damage to DNA and other cellular components. Researchers observed that cancer patients often have low blood levels of vitamin E. There are claims that vitamin E increases the effectiveness of some **chemotherapy** drugs and may reduce some side effects from chemotherapy and **radiation therapy** used to treat cancer. Others have argued that high doses of vitamin E interfere with the effectiveness of both radiation and chemotherapy. However, most studies have indicated that vitamin E supplements have no effect on the prevention or treatment of cancer. In fact, a 2011 follow-up of a clinical trial involving 35,000 men concluded that those who took vitamin E supplements were more likely to develop **prostate cancer**.

Studies of other health claims for vitamin E supplements have yielded equally contradictory results. These claims include easing inflammation from arthritis, speeding healing from **burns** or surgery, slowing the progression of Parkinson's and Alzheimer's diseases, preventing or treating **cataracts** and age-related **macular degeneration**, and protecting against the damaging effects of pollution and sun exposure. Although some of the confusion surrounding the effects of vitamin E supplements may stem from the many different forms of vitamin E and a lack of knowledge about the specific functions of these different forms, it is now generally accepted that vitamin E supplements are not beneficial and may be harmful. Supplements are usually only necessary or recommended for people with vitamin E deficiency or a condition that puts them at risk for a deficiency.

Vitamin E deficiency

Vitamin E deficiency is almost as controversial as the purported benefits from vitamin E supplementation. Severe vitamin E deficiency damages nerves, especially those in the hands and feet. Deficiency can cause loss of balance and coordination and muscle weakness. It can also damage the retina of the eye, leading to vision loss. Over the long term, vitamin E deficiency may progress to blindness, heart disease, nerve damage, and impaired thinking.

True vitamin E deficiency is believed to be rare and to occur almost exclusively in people with an inherited or acquired condition that impairs their ability to absorb the vitamin. It is generally assumed that almost all healthy people in the developed world obtain enough vitamin E through their diet to prevent symptoms of vitamin E deficiency. However, although signs of vitamin E deficiency may develop quickly in children, symptoms can take years to become apparent in adults. Furthermore, there is some debate about the prevalence of subclinical vitamin E deficiency that does not cause obvious symptoms.

Those at greatest risk for vitamin E deficiency include:

- severely premature infants weighing less that 3 lb. 4 oz. (1,500 g) at birth
- people with diseases such as Crohn's disease, inflammatory bowel disease, or cystic fibrosis that interfere with the absorption of fat from the intestine
- people who have had part of their stomach or intestine surgically removed
- people eating very low-fat diets for an extended time
- people with anorexia nervosa (self-starvation)
- people with the rare inherited disorders abetalipoproteinemia or ataxia and vitamin E deficiency (AVED), both of which prevent normal utilization of vitamin E

Precautions

Some experts believe that the UL for vitamin E in healthy adults of 1,500 IU daily is too high, especially since it is based on research done in the 1950s and since some studies have found that much lower daily amounts can increase the death rate. The recommended upper daily limit in the United Kingdom is 800 IU.

WWW.BOOKBAZ.IR

KEY TERMS

Adequate intake (AI)—The daily average intake level of a nutrient that is likely to be adequate for a healthy, moderately active individual, as determined by the U.S. Institute of Medicine.

Alpha-tocopherol—The most biologically active form of vitamin E.

Antioxidant—Substances, such as vitamin E, that prevent or reduce cellular damage from reactive oxygen species such as free radicals.

Dietary reference intake (DRI)—A system of nutritional recommendations used by the Institute of Medicine of the U.S. National Academy of Sciences and the U.S. Department of Agriculture.

Dietary supplement—A product, such as a vitamin, mineral, herb, amino acid, or enzyme, that is consumed in addition to diet with the expectation that it will maintain or improve health.

Enriched—Having some of the nutrients added back that were lost during processing.

Fat-soluble vitamin—A vitamin that dissolves in fat and can be stored in body fat or the liver.

Fortified—Having added nutrients, such as vitamin E, that do not occur naturally in that particular food.

Free radicals—Reactive atoms or groups of atoms that damage cells, proteins, and DNA.

International unit (IU)—An agreed-upon standard of physiological activity for a given biological substance such as a vitamin; 1 mg of vitamin E as alpha-tocopherol is approximately 1.5 IU.

Recommended dietary allowance (RDA)—The approximate amount of a nutrient that should be ingested daily.

Tolerable upper intake level (UL)—The highest daily intake level of a nutrient that is unlikely to cause adverse health effects in almost all individuals in the general population, as determined by the U.S. Institute of Medicine.

Antioxidant supplements can be harmful and are toxic at high doses. They can bind to minerals in the diet, preventing their absorption, and may increase the risk of lung cancer. Large doses of vitamin E increase the risk of bleeding. Vitamin E supplements should not be taken within one month of surgery because of this risk. People who are vitamin K-deficient, who have liver damage, or who have a history of bleeding **ulcers** should be wary of vitamin E supplements. Although the effects of vitamin E on chemotherapy drugs and radiation therapy are controversial, most oncologists advise their patients to avoid antioxidant vitamin and mineral supplements during treatment.

The vitamin E in multivitamins is generally considered to be safe, as long as it does not exceed the RDA. More than 800 IU or 533 mg taken daily over the long-term may cause nausea, **vomiting**, **diarrhea**, and stomach **pain**. Other uncommon side effects of vitamin E supplementation include damage to the retina, breast soreness, **fatigue**, emotional disturbances, and thyroid hormone disturbances. High doses of vitamin E may slow the absorption of vitamins A, D, and K, leading to deficiencies. Vitamin E supplements may also cause heart problems or interfere with blood clotting.

Interactions

Large doses of vitamin E increase the chance of bleeding. People who are taking blood-thinning medications such as warfarin (Coumadin), heparin, or clopidogrel (Plavix), or **aspirin** or **nonsteroidal anti-inflammatory drugs** (NSAIDs) such as ibuprofen or naproxen, are advised against taking large doses of vitamin E.

Many other drugs may interact with vitamin E including:

- bile acid sequestrants and possibly statins taken to lower cholesterol
- the weight-loss drug orlistat
- the fat substitute olestra
- tricyclic antidepressants
- antipsychotic medications
- beta-blockers for treating high blood pressure
- calcium channel blockers
- cisapride and omeprazole for stomach acid
- fluoxetine (Prozac)
- fexofenadine (Allegra) for allergies

Complications

No complications are expected when vitamin E is used in the recommended amounts.

Vitamin K

Definition

Vitamin K is a fat-soluble organic compound that the body needs to remain healthy. Although bacteria in the human intestine make some vitamin K, it is not nearly enough to meet the body's needs, so people must get most of their vitamin K from foods in their diet.

Purpose

The liver needs vitamin K to make factors that regulate blood clotting. Vitamin K may also play a role in maintaining strong bones and preventing **osteoporosis**.

Description

Vitamin K is not a single substance but a collection of chemically similar compounds called naphthoquinones. Vitamin K_1, called phylloquinone, is the natural form of vitamin K. It is found in plants and is the main source of vitamin K in the human diet. Vitamin K_2 compounds, called menaquinones, are made by bacteria that live in the human intestine. Researchers originally thought that bacteria in the gut provided a substantial percentage of human vitamin K needs, but later research revealed that these bacteria provided only a small amount and that people should get most of their vitamin K from diet. Vitamin K_1 is manufactured synthetically and sold under many brand names as a dietary supplement. Vitamin K is also included in many multivitamins. A synthetic water-soluble form of vitamin K called K_3 or menadione, is not allowed in dietary supplements in the United States because of the risk of serious side effects.

Vitamin K's role in health

Vitamin K is necessary for normal blood clotting (coagulation). In the liver, it is converted into more

(Table by PreMediaGlobal. © Cengage Learning.)

than half a dozen coenzymes that are essential to the formation of **blood clots**.

Vitamin K is routinely given to newborns in order to prevent bleeding known as hemorrhagic disease of the newborn (HDN) or vitamin K deficiency bleeding (VKDB), which can occur during the early weeks of life. Although this type of bleeding occurs only in 0.25%–1.7% of untreated newborns, it can be fatal. Since 1961, the American Academy of Pediatrics has recommended that all newborns receive a single 0.5–1.0 mg injection of vitamin K_1 immediately after birth. If parents refuse the injection, infants can be given two doses orally (2 mg each). A few researchers have questioned whether this early injection of vitamin K increases the risk of developing childhood cancer; however, a number of well-designed studies have found no link between the two.

There is some evidence that vitamin K may play a role in maintaining strong bones. Certain proteins that regulate the cells (osteoblasts) that deposit **calcium** and other **minerals** in bone appear to be dependent on vitamin K. If this is true, vitamin K may play a role in preventing osteoporosis. Definitive evidence has yet to be found, but a list of current and completed clinical trials investigating the use of vitamin K in treating osteoporosis may be found online at ClinicalTrials.gov.

Normal vitamin K requirements

The U.S. Institute of Medicine (IOM) of the National Academy of Sciences develops values called dietary reference intakes (DRIs) for **vitamins** and minerals. The DRIs consist of three sets of numbers: the recommended dietary allowance (RDA), which defines the average daily amount of the nutrient needed to meet the health needs of 97%–98% of the population; adequate intake (AI), an estimate set when there is not enough information to determine an RDA; and tolerable upper intake levels (UL), the average maximum amounts that can be taken daily without risking negative side effects. The DRIs are calculated for children, adults, and pregnant and **breastfeeding** women.

The IOM has not set RDA values for vitamin K due to the lack of scientific information. Instead, in 2000, it set AI levels for all age groups. AI levels for vitamin K are measured by weight (micrograms or mcg). No UL levels have been set for vitamin K. Large amounts of vitamin K_1 do not appear to cause blood clotting or other side effects. However, K_3 is associated with health risks, especially to children. It is banned by the U.S. Food and Drug Administration.

The following are the AIs for vitamin K for healthy individuals:

- infants 0–6 months: 2 mcg
- infants 7–12 months: 2.5 mcg
- children 1–3 years: 30 mcg
- children 4–8 years: 55 mcg
- children 9–13 years: 60 mcg
- children 14–18 years: 75 mcg
- men age 19 and older: 120 mcg
- women age 19 and older: 90 mcg
- pregnant and breastfeeding women age 18 and younger: 75 mcg
- pregnant and breastfeeding women age 19 and older: 90 mcg

Sources of vitamin K

Vitamin K is found in the largest quantities in green, leafy vegetables. Little vitamin K is lost during cooking, but more is lost when foods are frozen. The following list gives the approximate vitamin K_1 content of some common foods:

- parsley, fresh, 2 tablespoons: 120 mcg
- spinach, cooked, 1/2 cup: 445 mcg
- kale, cooked, 1/2 cup: 530 mcg
- turnip greens, cooked, 1/2 cup: 265 mcg
- Swiss chard, cooked, 1/2 cup: 285 mcg
- Brussels sprouts, cooked, 1/2 cup: 110 mcg
- broccoli, cooked, 1/2 cup: 77 mcg
- asparagus, cooked, 1/2 cup: 46 mcg
- celery, raw, 1/2 cup: 18 mcg
- carrots, raw, 1/2 cup: 8 mcg
- miso, 1 ounce: 4 mcg
- milk, 2%, 1 cup: 5 mcg
- dietary supplements: 10–120 mcg

Vitamin K deficiency

Vitamin K deficiency is extremely rare in healthy people. It can, however, occur in individuals who have disorders that interfere with the absorption of nutrients from the intestine. Signs of vitamin K deficiency include easy bruising, excessive bleeding, and slow clotting. People who are at higher risk for vitamin K deficiency include:

- people with gastrointestinal diseases such as Crohn's disease, cystic fibrosis, inflammatory bowel disease, or ulcerative colitis
- people who have had part of their stomach or intestine surgically removed for weight loss or other reasons
- people with liver damage
- people with alcoholism
- people who must take high doses of antibiotics for a long period of time

Precautions

People who take blood-thinning drugs, especially warfarin (Coumadin), should discuss their vitamin K needs with their healthcare provider. They may need to restrict their intake of vitamin K. The purpose of blood-thinning drugs is to keep the blood from forming clots in the veins and arteries. Since vitamin K helps blood to clot, high levels of vitamin K in the diet may work against blood-thinning drugs and reduce their effect. Individuals taking these drugs are encouraged to keep their daily intake of vitamin K steady at or slightly below the AI level. In addition, they should have their international normalized ratio (INR) and **prothrombin time** (PT), both measures of blood-clotting potential, checked regularly.

Injections of vitamin K_3 (menadione) are banned in the United States because they can cause liver damage and rupture of red blood cells in infants and children.

People considering taking vitamin K-containing supplements should first consult with their healthcare provider.

KEY TERMS

Clotting factors—Also known as coagulation factors; proteins in plasma that serve to activate various parts of the blood-clotting process.

Coenzyme—Also called a cofactor, a small nonprotein molecule that binds to an enzyme and catalyzes (stimulates) enzyme-mediated reactions.

Dietary supplement—A product, such as a vitamin, mineral, herb, amino acid, or enzyme, that is intended to be consumed in addition to an individual's diet with the expectation that it will improve health.

Enzyme—A protein that changes the rate of a chemical reaction within the body without being depleted in the reaction.

Fat-soluble vitamin—A vitamin that dissolves in and can be stored in body fat or the liver.

Osteoporosis—A condition found in older individuals in which bones decrease in density and become fragile and more likely to break. It can be caused by lack of vitamin D and/or calcium in the diet.

Vitamin—A nutrient that the body needs in small amounts to remain healthy but that the body cannot manufacture for itself and must acquire through diet.

Interactions

In addition to interfering with blood-thinning drugs, vitamin K may interact with the following:

- Some broad-spectrum antibiotics (antibiotics that kill a wide variety of bacteria) may decrease the amount of vitamin K_2 produced in the intestines.
- Aspirin (salicylates) taken in high doses over a long time may increase the body's need for vitamin K.
- Cholestyramine (Questran) and mineral oil may decrease vitamin K absorption.
- Quinine may increase the body's need for vitamin K
- Orlistat (Xenical, Alli) is likely to decrease Vitamin K absorption.

WWW.BOOKBAZ.IR

- Vitamin K may decrease the effectiveness of blood-thinning herbs such as American ginseng (*P. quinquefolius*), alfalfa (*Medicago sativa*), and angelica (*Angelica archangelica*).
- Olestra, a compound that reduces fat absorption, decreases the absorption of vitamin K. The FDA requires all foods containing olestra to be fortified with the fat-soluble vitamins A, D, E, and K.
- Coenzyme Q-10 also promotes blood clotting, and taking coenzyme Q-10 supplements may increase blood-clotting abilities.
- High intake of vitamin E (more than 800 IU per day) may counteract the effects of vitamin K and can increase the risk of bleeding, especially in people taking warfarin or other blood-thinning drugs.

Complications

No complications are expected from vitamin K, especially when most of the vitamin K comes from dietary sources. However, pregnant and breastfeeding women should avoid taking vitamin K supplements. In addition, people taking blood-thinning drugs should carefully monitor their intake of vitamin K so that they do not increase the chance of developing blood clots.

Vitamin K deficiency bleeding (VKDB), formerly called hemorrhagic disease of the newborn (HDN), is a bleeding condition seen in some newborns. There are three forms:

- early onset, usually seen only in babies whose mothers took certain drugs during pregnancy, including warfarin, anticonvulsant drugs, antituberculosis drugs, or select antibiotics
- classical, which typically manifests within the first week of life
- late onset, found most often in breastfed infants who did not receive a vitamin K injection

Ensuring that newborns receive adequate vitamin K at birth, whether by injection or oral dosage, is the best prevention against VKDB.

Vitamin poisoning *see* **Vitamin toxicity**

Vitamin tests

Definition

Vitamin tests measure the levels of certain **vitamins** in an individual's blood. They are generally used to aid in the diagnosis of vitamin deficiencies or in detecting toxic amounts of a vitamin in a patient's system.

Purpose

Vitamins are components of food that are needed for growth, reproduction, and maintaining good health. The vitamins include **vitamin D**, **vitamin E**, **vitamin A**, and **vitamin K**, which are the fat-soluble vitamins, and folate, vitamin B_{12}, biotin, vitamin B_6, niacin, thiamin, riboflavin, pantothenic acid, and ascorbic acid, which are the water-soluble vitamins. Vitamins are required in the diet in only tiny amounts, in contrast to the energy components of the diet, such as sugars, starches, and fats. However, not receiving sufficient quantities of a certain vitamin can be devastating, resulting in vitamin deficiency diseases such as **scurvy**, **pellagra**, or **rickets**. Conversely, consuming too much of a certain vitamin can be toxic to a person's system. Vitamin tests are used to assess the level of certain vitamins in an individual's blood so that doctors can more accurately diagnose vitamin deficiency diseases or vitamin overdoses and devise effective therapy. The vitamins that are most commonly measured by doctors are folate, vitamin B_{12}, vitamin K, vitamin D, and vitamin A.

Description

Most of the vitamin tests are conducted by acquiring a sample of blood, and then preparing plasma or serum from the blood sample. Each vitamin occurs at extremely small concentrations when compared to levels of most other molecules in the blood. Blood contains a great number of chemicals and molecules, and many of these tend to interfere with the vitamin tests. For this reason, a procedure that separates the vitamin from contaminating substances is usually performed immediately prior to conducting the actual test. Most laboratories use high pressure liquid chromatography (HPLC), also called high performance liquid chromatography, as this purification step. In HPLC, the sample is pumped at high pressure through a tube lined with an absorbent material, to which the different molecules cling at different rates. Following separation or purification by HPLC, the vitamin is detected by a color reaction or fluorescence reaction. In these reactions, the amount of color or fluorescence that is formed is proportional to the amount of vitamin in the sample, allowing the analyst to calculate the amount of vitamin present in the original sample. In the case of some vitamins, the purified vitamin is reacted with a special chemical (reagent) prior to detection.

Levels of some vitamins may be measured indirectly by a biological test that mimics the actual function of the vitamin in the body. Riboflavin status is often measured by a test in which the rate by which a certain enzyme converts one molecule into another indicates how much Vitamin B_2 is present in a person's blood. Vitamin K is often measured by a test that times how long it takes for a spontaneous blood clot to form in a prepared sample. Vitamin E status is often measured by placing the red blood cells in a test tube, adding hydrogen peroxide, and assessing the resulting breakdown of the red blood cells. When a vitamin E deficiency exists, the red blood cells have a greater tendency to break.

Preparation

Most vitamin tests require no preparation; however, some may require that the patient fast for at least eight hours before giving a blood sample, or stop using some medications.

Normal results

The values that are considered to be normal for each vitamin can vary slightly. This variability can arise from different testing machines or from different types of chemistry that are used in conducting the vitamin assays. In interpreting data on plasma vitamin levels, it should also be noted that different normal ranges may exist for different age groups and genders. For example, the normal range for plasma vitamin B_6 is 7–52 nanograms per milliliter (ng/mL) for males and 2–26 ng/mL for females.

The normal ranges for levels of certain vitamins are as follows. Please note that, by convention, the units referring to the levels of each of the vitamins may differ from each other. The units picogram/milliliter (pg/mL), nanogram/milliliter (ng/mL), and micrograms per deciliter (micrograms/dL) refer to the weight of vitamin in the specified volume. The units nanomoles/liter (nmol/L) and micromoles/liter (M/L) refer to the concentration of vitamin in the specified volume.

- folate (folic acid): 3.1–18.0 ng/mL

WWW.BOOKBAZ.IR

- vitamin B_{12}: 200–1100 pg/mL
- thiamin: 9–44 nmol/L
- riboflavin: 6.2–39 nmol/L
- vitamin B_6: 7–52 ng/mL
- vitamin C (asorbic acid): 28–84 M/L
- vitamin A: 28–94 micrograms/dL
- vitamin D (25-hydroxy-vitamin D): 25–50 ng/mL
- vitamin K: 80–1160 pg/mL

Abnormal results

In all cases, abnormal results fall below or above the normal concentration range. However, values that are considered to be borderline or severely abnormal can differ according to the discretion of the medical laboratory or physician.

Vitamin toxicity

Definition

Vitamin toxicity is a condition in which a person develops symptoms as side effects from taking massive doses of **vitamins**. Vitamins vary in the amounts that are required to cause toxicity and in the specific symptoms that result. Vitamin toxicity, which is also called hypervitaminosis or vitamin **poisoning**, is becoming more common in developed countries because of the popularity of vitamin supplements. Many people treat themselves for minor illnesses with large doses (megadoses) of vitamins.

Description

Overview

Vitamins are organic molecules in food that are needed in small amounts for growth, reproduction, and the maintenance of good health. Some vitamins can be dissolved in oil or melted fat. These fat-soluble vitamins include **vitamin D**, **vitamin E**, **vitamin A** (retinol), and **vitamin K**. Other vitamins can be dissolved in water. These water-soluble vitamins include folate (**folic acid**), vitamin B_{12}, biotin, vitamin B_6, niacin, thiamin, riboflavin, pantothenic acid, and vitamin C (ascorbic acid). Taking too much of any vitamin can produce a toxic effect. Vitamin A and vitamin D are the most likely to produce hypervitaminosis in large doses, while riboflavin, pantothenic acid, biotin, and vitamin C appear to be the least likely to cause problems.

Vitamins in medical treatment

Vitamin supplements are used for the treatment of various diseases or for reducing the risk of certain diseases. For example, moderate supplements of folic acid appear to reduce the risk for certain **birth defects** (neural tube defects) and possibly reduce the risk of cancer. Therapy for diseases brings with it the risk for irreversible vitamin toxicity only in the case of vitamin D. This vitamin is toxic at levels which are only moderately greater than the recommended dietary allowance (RDA). Niacin is commonly used as a drug for the treatment of **heart disease**. Niacin is far less toxic than vitamin D. Vitamin toxicity is not a risk with medically supervised therapy using any of the other vitamins.

Vitamin megadoses

With the exception of folic acid supplements, the practice of taking vitamin supplements by healthy individuals has little or no relation to good health. Most adults in the United States can obtain enough vitamins by eating a well-balanced diet. It has, however, become increasingly common for people to take vitamins at levels far greater than the RDA. These high levels are sometimes called vitamin megadoses. Megadoses are harmless for most vitamins. But in the cases of a few of the vitamins—specifically vitamin D, vitamin A, and vitamin B_6—megadoses can be harmful or fatal. Researchers have also started to look more closely at megadoses of vitamin C and of vitamin E, since indirect evidence suggests that these two vitamins may reduce the risks of cancer, heart disease, and **aging**. It is not yet clear whether megadoses of either of these vitamins have any influence on health. Some experts think that megadoses of vitamin C may protect people from cancer. On the other hand, other researchers have gathered indirect evidence that vitamin C megadoses may cause cancer.

Causes and symptoms

Fat-soluble vitamins

VITAMIN D. Vitamin D and vitamin A are the most toxic of the fat-soluble vitamins. The symptoms of vitamin D toxicity are nausea, **vomiting**, **pain** in the joints, and loss of appetite. The patient may experience

constipation alternating with **diarrhea**, or have tingling sensations in the mouth. The toxic dose of vitamin D depends on its frequency. In infants, a single dose of 15 mg or greater may be toxic, but it is also the case that daily doses of 1.0 mg over a prolonged period may be toxic. In adults, a daily dose of 1.0–2.0 mg of vitamin D is toxic when consumed for a prolonged period. A single dose of about 50 mg or greater is toxic for adults. The immediate effect of an overdose of vitamin D is abdominal cramps, **nausea and vomiting**. Toxic doses of vitamin D taken over a prolonged period of time result in irreversible deposits of **calcium** crystals in the soft tissues of the body that may damage the heart, lungs, and kidneys.

VITAMIN A. Vitamin A toxicity can occur with long-term consumption of 20 mg of retinol or more per day. The symptoms of vitamin A overdosing include accumulation of water in the brain (**hydrocephalus**), vomiting, tiredness, constipation, bone pain, and severe headaches. The skin may acquire a rough and dry appearance, with hair loss and brittle nails. Vitamin A toxicity is a special issue during **pregnancy**. Expectant mothers who take 10 mg vitamin A or more on a daily basis may have an infant with birth defects. These birth defects include abnormalities of the face, nervous system, heart, and thymus gland. It is possible to take in toxic levels of vitamin A by eating large quantities of certain foods. For example, about 30 grams of beef liver, 500 grams of eggs, or 2,500 grams of mackerel would supply 10 mg of retinol. The livers of polar bears and other arctic animals may contain especially high levels of vitamin A.

VITAMIN E. Megadoses of vitamin E may produce headaches, tiredness, double vision, and diarrhea in humans. Studies with animals fed large doses of vitamin E have revealed that this vitamin may interfere with the absorption of other fat-soluble vitamins. The term absorption means the transfer of the vitamin from the gut into the bloodstream. Thus, large doses of vitamin E consumed over many weeks or months might result in deficiencies of vitamin D, vitamin A, and vitamin K.

VITAMIN K. Prolonged consumption of megadoses of vitamin K (menadione) results in anemia, which is a reduced level of red blood cells in the bloodstream. When large doses of menadione are given to infants, they result in the deposit of pigments in the brain, nerve damage, the destruction of red blood cells (hemolysis), and death. A daily injection of 10 mg of menadione into an infant for three days can kill the child. This tragic fact was discovered during the early days of vitamin research, when newborn infants were injected with menadione to prevent a disease known as hemorrhagic disease of the newborn. Today a different form of vitamin K is used to protect infants against this disease.

Water-soluble vitamins

FOLATE. Folate occurs in various forms in food. There are over a dozen related forms of folate. The folate in oral vitamin supplements occurs in only one form, however—folic acid. Large doses of folic acid (20 grams/day) can result in eventual kidney damage. Folate is considered, however, to be relatively nontoxic, except in cases where folate supplementation can lead to **pernicious anemia**.

VITAMIN B_{12}. Vitamin B_{12} is important in the treatment of pernicious anemia. Pernicious anemia is more common among middle-aged and older adults; it is usually detected in patients between the ages of 40 and 80. The disease affects about 0.1% of all persons in the general population in the United States, and about 3% of the elderly population. Pernicious anemia is treated with large doses of vitamin B_{12}. Typically, 0.1 mg of the vitamin is injected each week until the symptoms of pernicious anemia disappear. Individuals then take oral doses of vitamin B_{12} for the rest of their life. Although vitamin B_{12} toxicity is not an issue for patients being treated for pernicious anemia, treatment of these patients with folic acid may cause problems. Specifically, pernicious anemia is often first detected because the patient feels weak or tired. If the anemia is not treated, the patient may suffer irreversible nerve damage. The problem with folic acid supplements is that the folic acid treatment prevents the anemia from developing, but allows the eventual nerve damage to occur.

VITAMIN B_6. Vitamin B_6 is clearly toxic at doses about 1,000 times the RDA. Daily doses of 2–5 grams of one specific form of this vitamin can produce difficulty in walking and tingling sensations in the legs and soles of the feet. Continued megadoses of vitamin B_6 result in further unsteadiness, difficulty in handling small objects, and numbness in the hands. When the high doses are stopped, recovery begins after two months. Complete recovery may take two to three years.

VITAMIN C. The RDA for vitamin C in adults is 60 mg per day. Large doses of vitamin C are considered to be toxic in persons with a family history of or tendency to form **kidney stones** or gallbladder stones. Kidney and gallbladder stones usually consist of calcium oxalate. Oxalate occurs in high concentrations in foods such as cocoa, chocolate, rhubarb, and spinach. A fraction of the vitamin C in the body is normally

WWW.BOOKBAZ.IR

KEY TERMS

Absorption—The transfer of a vitamin from the digestive tract to the bloodstream.

Ascorbic acid—Another name for vitamin C.

Hypercalcemia—A condition marked by abnormally high levels of calcium in the blood. It is an issue during vitamin D toxicity.

Hypervitaminosis—Another name for vitamin toxicity.

Megadose—A very large dose of a vitamin, taken by some people as a form of self-medication.

Menadione—A synthetic form of vitamin K. It is sometimes called vitamin K_3.

Recommended Dietary Allowance (RDA)—The quantities of nutrients in the diet that are needed for good health. RDAs are established by the Food and Nutrition Board of the National Academy of Sciences and may be revised every few years.

Retinol—Another name for vitamin A.

broken down in the body to produce oxalate. A daily supplement of 3.0 grams of vitamin C has been found to double the level of oxalate that passes through the kidneys and is excreted into the urine.

NIACIN. The RDA for niacin is 15–19 mg per day in adults. Niacin comes in two forms, nicotinic acid and nicotinamide. Either form can satisfy the adult requirement for this vitamin. Nicotinic acid, however, is toxic at levels of 100 times the RDA. It can cause flushing of the skin, nausea, diarrhea, and liver damage. Flushing is an increase in blood passing through the veins in the skin, due to the dilation of arteries passing through deeper parts of the face or other parts of the body. In spite of the side effects, however, large doses of nicotinic acid are often used to lower blood **cholesterol** in order to prevent heart disease. Nicotinic acid results in a lowering of LDL-cholesterol ("bad cholesterol"), an increase in HDL-cholesterol ("good cholesterol"), and a decrease in plasma **triglycerides**. Treatment involves daily doses of 1.5–4.0 grams of nicotinic acid per day. Flushing of the skin occurs as a side effect when nicotinic acid therapy is started, but may disappear with continued therapy.

Diagnosis

The diagnosis of vitamin toxicity is usually made on the basis of the patient's dietary or medical history. Questioning patients about their use of vitamin supplements may shed light on some of their physical symptoms. With some vitamins, the doctor can confirm the diagnosis by ordering blood or urine tests for specific vitamins. When large amounts of water-soluble vitamins are consumed, a large fraction of the vitamin is absorbed into the bloodstream and promptly excreted into the urine. Fat-soluble vitamins are more likely to be absorbed into the bloodstream and deposited in the fat and other tissues. In the cases of both water-soluble and fat-soluble vitamins, any vitamin not absorbed by the intestines is excreted in the feces. Megadoses of many of the vitamins produce diarrhea because the non-absorbed nutrient draws water out of the body and into the gut, resulting in the loss of this water from the body.

Treatment

In all cases, treatment of vitamin toxicity requires discontinuing vitamin supplements. Vitamin D toxicity needs additional action to reduce the calcium levels in the bloodstream because it can cause abnormally high levels of plasma calcium (**hypercalcemia**). Severe hypercalcemia is a medical emergency and may be treated by infusing a solution of 0.9% **sodium** chloride into the patient's bloodstream. The infusion consists of two to three liters of salt water given over a period of one to two days.

Prognosis

The prognosis for reversing vitamin toxicity is excellent for most patients. Side effects usually go away as soon as overdoses are stopped. The exceptions are severe vitamin D toxicity, severe vitamin A toxicity, and severe vitamin B_6 toxicity. Too much vitamin D leads to deposits of calcium salts in the soft tissue of the body, which cannot be reversed. Birth defects due to vitamin A toxicity cannot be reversed. Damage to the nervous system caused by megadoses of vitamin B_6 can be reversed, but complete reversal may require a recovery period of over a year.

Prevention

Vitamin toxicity can be prevented by minimizing the use of vitamin supplements. If vitamin D supplements are being used on a doctor's orders, vitamin toxicity can be prevented by monitoring the levels of plasma calcium. The development of hypercalcemia with vitamin D treatment indicates that the patient is at risk for vitamin D toxicity.

Ken R. Wells

Essential vitamins

Vitamin	Benefits
Vitamin A (beta carotene)	Promotes growth and repair of body tissues; reduces susceptibility to infections; aids in bone and teeth formation; maintains smooth skin
Vitamin B_1 (thiamin)	Promotes growth and muscle tone; aids in the proper functioning of the muscles, heart, and nervous system; assists in digestion of carbohydrates
Vitamin B_2 (riboflavin)	Maintains good vision and healthy skin, hair, and nails; assists in formation of antibodies and red blood cells; aids in carbohydrate, fat, and protein metabolism
Vitamin B_3 (niacin)	Reduces cholesterol levels in the blood; maintains healthy skin, tongue, and digestive system; improves blood circulation; increases energy
Vitamin B_5 (pantothenic acid)	Fortifies white blood cells; supports the body's resistance to stress; builds cells
Vitamin B_6 (pyridoxine)	Aids in the synthesis and breakdown of amino acids and the metabolism of fats and carbohydrates; supports the central nervous system; maintains healthy skin
Vitamin B_7 (biotin)	Aids in the metabolism of proteins and fats; promotes healthy skin
Vitamin B_{12} (cobalamin)	Promotes growth in children; prevents anemia by regenerating red blood cells; aids in the metabolism of carbohydrates, fats, and proteins; maintains healthy nervous system
Folic acid (folate; considered a B-complex vitamin)	Promotes the growth and reproduction of body cells; aids in the formation of red blood cells and bone marrow
Vitamin C (ascorbic acid)	One of the major antioxidants; essential for healthy teeth, gums, and bones; helps to heal wounds, fractures, and scar tissue; builds resistance to infections; assists in the prevention and treatment of the common cold; prevents scurvy
Vitamin D	Improves the absorption of calcium and phosphorous (essential in the formation of healthy bones and teeth); maintains nervous system
Vitamin E	A major antioxidant; supplies oxygen to blood; provides nourishment to cells; prevents blood clots; slows cellular aging
Vitamin K	Prevents internal bleeding; reduces heavy menstrual flow

(Table by PreMediaGlobal. © Cengage Learning®.)

Vitamins

Definition

Vitamins are organic compounds found in plants and animals that are necessary in small quantities for life and health. Thirteen different vitamins have been identified as necessary for humans. The body can make small quantities of two of these vitamins, vitamins D and K. All other vitamins must be obtained either from food or from dietary supplements.

Purpose

Each of the 13 vitamins has specific functions, and taken together vitamins play a role in almost every function in the body. They help convert food to energy and

WWW.BOOKBAZ.IR

are involved in processes as diverse as blood clotting, vision, reproduction, and transmission of nerve impulses.

Description

For centuries before vitamins were formally discovered, people knew that eating certain foods prevented certain diseases. For example, the ancient Egyptians knew that eating liver (later shown to be high in **vitamin A**) prevented night blindness. Sailors on long voyages often developed a serious disease called **scurvy**. James Lind, a Scottish surgeon who sailed with the British navy, conducted the first controlled experiment on vitamins in 1753. He supplemented the regular diet of four groups of sailors with four different foods. The group that received oranges and lemons as supplements did not develop scurvy, while the other three groups did. Although Lind did not know why citrus fruit was essential to health (it is high in vitamin C, and scurvy is caused by vitamin C deficiency), he recognized that it contained some substance that the sailors needed.

Water-soluble vitamins

Humans need nine water-soluble vitamins. These vitamins dissolve in water and are not stored in the body for long periods. Most excess water-soluble vitamins are removed by the kidneys and leave the body in urine. In general, B vitamins tend to be involved in reactions that convert nutrients to energy and reactions that synthesize new molecules. There are gaps in the numbering of the B-complex vitamins, because compounds originally named as vitamins, such as B4 (adenine), were renamed after further research showed that they did not meet the definition of a vitamin. Water-soluble vitamins include:

- Vitamin B_1 (thiamin): needed to convert carbohydrates to energy
- Vitamin B_2 (riboflavin): helps breakdown proteins, fats, and carbohydrates and make other vitamins and minerals available to the body
- Vitamin B_3 (niacin): helps the body process fats and proteins
- Vitamin B_5 (pantothenic acid): helps regulate the chemical reactions that produce energy
- Vitamin B_6 (pyridoxine): involved in the transmission of nerve impulses, formation and functioning of red blood cells, and creation of new cells
- Vitamin B_{12} (cobalamin): necessary for healthy red blood cells, creating new deoxyribose nucleic acid (DNA), and maintaining nerve cells
- Vitamin C (ascorbic acid): helps form cartilage and connective tissue; as an antioxidant, protects cells from free radical damage
- Vitamin H (biotin): joins with enzymes that regulate the breakdown of foods and their use in the body
- Folic acid (folate): helps make new cells; important in development of the fetal nervous system

Fat-soluble vitamins

Humans need four fat-soluble vitamins. Unlike water-soluble vitamins, fat-soluble vitamins can be stored in the body. High levels of these vitamins can cause health problems. Below is a list of the water-soluble vitamins and a very brief description of their importance to health. In general, the fat-soluble vitamins have antioxidant activity that helps protect cells from damage. Fat-soluble vitamins include:

- Vitamin A (retinol): needed for vision, a healthy immune system, development of the fetus, tissue repair; as an antioxidant, protects cells from free radical damage
- Vitamin D (calciferol): involved in building bones, muscle contraction, and nerve impulse transmission
- Vitamin E (tocopherol): acts as an antioxidant to protect the body against damage caused by free radicals
- Vitamin K: needed for blood clotting

Vitamin supplements

Before the twentieth century, all vitamins had to come from food. Often individuals on limited **diets** with little variety developed vitamin deficiency diseases. The period from the 1920s to the 1940s was a time of active research on vitamins. Out of this research came a food fortification program in the United States that continues today. Beginning in the late 1930s, the addition of vitamins to common foods such as flour, milk, and breakfast cereal substantially reduced vitamin deficiency diseases. Commercially manufactured vitamin supplements also began to appear, and taking a daily multivitamin supplement became popular. By 2007, more than 100 million Americans regularly took some form of vitamin supplement.

Vitamin supplements come as tablets, capsules, and elixirs (liquids). Supplements can contain a single vitamin, a group of related vitamins that work together in the body (e.g., B-complex vitamins), or a mixture of vitamins and **minerals** (e.g., **vitamin D** and **calcium** that work together to build bones). Vitamins are also added to foods that can then be labeled "fortified" or "enriched." Many so-called functional foods,

or nutraceuticals, have added vitamins, minerals, and herbs.

In the United States, the Food and Drug Administration (FDA) regulates dietary supplements under the 1994 Dietary Supplement Health and Education Act (DSHEA). Under DSHEA, supplements are subject to the same regulation as food, which is much less rigorous than the regulation of prescription or over-the-counter drugs. Vitamin manufacturers do not have to prove that their products are safe or effective before they can be sold to the public. By contrast, manufacturers of conventional prescription and over-the-counter drugs must prove both safety and effectiveness in humans before their product can be marketed.

In 2007, ConsumerLab, an independent testing company in New York, evaluated 21 brands of multivitamins. They found that only 10 of these multivitamins contained all the vitamins and minerals in the quantities listed on the label. In addition, some brands contained contaminants, including lead. To get the most out of vitamin supplements, consumers should:

- Read the label carefully to understand exactly what is in the supplement.
- Avoid megadoses of vitamins. The daily value (DV) given on the label should be around 100% for each vitamin.
- Look for "USP" on the label. This means that the supplement meets the strength and purity standards of the U.S. Pharmacopeia, a testing organization.
- Check the expiration date.
- Stick with well-known brands.

Vitamin requirements

The United States Institute of Medicine (IOM) of the National Academy of Sciences has developed values called dietary reference intakes (DRIs) for most vitamins and minerals. The DRIs consist of three sets of values. The recommended dietary allowance (RDA) defines the average daily amount of the nutrient needed to meet the health needs of 97%–98% of the population. The adequate intake (AI) is an estimate set when there is not enough information to determine an RDA. The tolerable upper intake level (UL) is the average maximum amount that can be taken daily without risking negative side effects. The DRIs are calculated for children, adult men, adult women, pregnant women, and **breastfeeding** women.

Experts agree that vitamin supplements are not a substitute for nutrients from food. Most healthy people in developed countries who eat a varied diet high in fruits, vegetables, and whole grains get enough vitamins and do not need a vitamin supplement, although many take a daily multivitamin as "insurance." However, some groups do tend to need either general supplementation with a multivitamin or supplementation with specific vitamins to prevent vitamin deficiency diseases. People in these groups should discuss their vitamin requirements with their healthcare provider. They include:

- the elderly, especially those on restricted diets
- vegans, because they eat no animal products
- breastfed babies of vegan mothers
- people with lactose intolerance or those who do not eat dairy products
- people with alcoholism
- people who have had part of their stomachs or intestines surgically removed
- pregnant women or those who could become pregnant
- people with diseases that interfere with vitamin metabolism
- people taking drugs that interfere with vitamin metabolism

Vitamin excess

Although vitamins play an undeniable role in maintaining health, large doses of vitamins in healthy individuals can cause adverse effects. Almost all vitamin excess (hypervitaminosis) occurs because of supplementation; it is almost impossible to get too many vitamins from food. Although a great deal of advertising, especially on the Internet, suggests that megadoses of certain vitamins can improve athletic performance, prevent and treat chronic disease, delay **aging**, and increase longevity, there is little or no evidence from independent, well-controlled human clinical trials to support these claims. One exception is high dose niacin, which has been used to treat high blood **cholesterol** levels. Although niacin is very safe at normal doses, the levels needed to lower serum cholesterol, it has been associated with liver damage and, commonly, severe facial flushing. Otherwise, excess water-soluble vitamins are removed from the body in urine. Although large doses of water-soluble vitamins rarely cause health problems, they cannot be used by the body and are a waste of money. Fat-soluble vitamins that are stored in the body can build up to very high levels and cause serious health concerns.

Precautions

Both too little and too much of any of the 13 human vitamins may cause health consequences. People

WWW.BOOKBAZ.IR

KEY TERMS

B-complex vitamins—A group of water-soluble vitamins that often work together in the body. These include thiamin (B_1), riboflavin (B_2), niacin (B_3), pantothenic acid (B_5), pyridoxine (B_6), biotin (B_7 or vitamin H), folate/folic acid (B_9), and cobalamin (B_{12}).

Dietary supplement—A product, such as a vitamin, mineral, herb, amino acid, or enzyme, that is intended to be consumed in addition to an individual's diet with the expectation that it will improve health.

Free radical—A molecule with an unpaired electron that has a strong tendency to react with other molecules in DNA (genetic material), proteins, and lipids (fats), resulting in damage to cells. Free radicals are neutralized by antioxidants.

Functional food—Also called nutraceuticals, these products are marketed as having health benefits or disease-preventing qualities beyond their basic supply of energy and nutrients. Often these health benefits come in the form of added herbs, minerals, vitamins, etc.

Mineral—An inorganic substance found in the earth that is necessary in small quantities for the body to maintain health. Examples include zinc, copper, iron.

interested in taking a multivitamin or other vitamin supplement should first talk to a healthcare provider.

Interactions

The interactions among various vitamins, enzymes, coenzymes, drugs, and herbal supplements are complex and incompletely understood. People should consult with their healthcare provider before taking any dietary supplements, especially if they are taking prescription medications.

Complications

Vitamins acquired by eating fruits and vegetables promote health. No complications are expected from vitamins in food. Vitamin supplements may cause hypervitaminosis or interact with other supplements, prescription drugs, over-the-counter drugs, and herbal supplements in ways that cause undesirable side effects.

Vitiligo

Definition

Vitiligo is a condition in which a loss of cells that give color to the skin (melanocytes) results in smooth, white patches in the midst of normally pigmented skin.

Description

Vitiligo is a common, often inherited disorder characterized by areas of well-defined, milky white skin. People with vitiligo may have eye abnormalities and also have a higher incidence of thyroid disease, **diabetes mellitus**, and **pernicious anemia**. Vitiligo affects about 1-2% of the world's population. It is more easily observed in sun-exposed areas of the body and in darker skin types, but it affects any area of the body and all races. Vitiligo seems to affect men and women equally, although women more frequently seek treatment for the disorder.

Vitiligo may appear as one or two well-defined white patches or it may appear over large portions of the body. Typical sites for generalized vitiligo are areas surrounding body openings, bony areas, fingers, and toes. It can begin at any age but about 50% of the time it starts before the age of 20.

Loss of pigmentation is one characteristic of vitiligo, as seen on this woman's hand. *(Custom Medical Stock Photo, Inc.)*

Causes and symptoms

Vitiligo is a disorder with complex causes. People with vitiligo seem to inherit a genetic predisposition for the disorder, and the appearance of disorder can be brought on by a variety of precipitating causes. Many people report that their vitiligo first appeared following a traumatic or stressful event, such as an accident, job loss, death of a family member, severe **sunburn**, or serious illness. There are at least three theories about the underlying mechanism of vitiligo. One theory says nerve endings in the skin release a chemical that is toxic to the melanocytes. A second theory states that the melanocytes simply self-destruct. The third explanation is that vitiligo is a type of autoimmune disease in which the immune system targets the body's own cells and tissues.

The primary symptom of vitiligo is the loss of skin color. Hair growing from the affected skin areas also lacks color. In addition, people with vitiligo may have pigment abnormalities of the retina or iris of the eyes. A minority of patients also may have inflammation of the retina or iris, but vision is not usually impaired.

Diagnosis

The diagnosis of vitiligo is usually made by observation. Progressive, white areas found at typical sites point to a diagnosis of vitiligo. If the diagnosis is not certain, the doctor will test for other conditions which can mimic vitiligo, such as chemical leukoderma or

WWW.BOOKBAZ.IR

KEY TERMS

Autoimmune disease—A condition in which something triggers the immune system to react against and attack the body's own tissues.

Autologous transplantation—A procedure wherein the person donates blood or tissue to themselves.

Iris—The colored part of the eye.

Pernicious anemia—A disease in which red blood cells are abnormally formed due to the body's inability to absorb vitamin B_{12}.

Retina—The innermost layer of the eye, it contains the rods and cones, specialized light-sensitive cells.

systemic lupus erythematosus. If the tests rule out other conditions, vitiligo is confirmed.

Treatment

Vitiligo cannot be cured, but it can be managed. Cosmetics can be used to improve the appearance of the white areas not covered by clothing. **Sunscreens** prevent burning of the affected areas and prevent the normal skin around the patches from becoming darker. Skin creams and oral medications are available for severe cases, but they have side effects that may make them undesirable. Autologous transplantation of skin is an option for those who are severely affected. Bleaching or depigmentation of the normal skin is another option.

In addition to treating the skin, attention should be paid to the psychological well-being of the individual. Extreme cases of vitiligo can be unattractive and may affect a person's outlook and social interactions.

Prognosis

The condition is usually gradually progressive. Sometimes the patches grow rapidly over a short period, and then the condition remains stable for many years.

Prevention

No measures are currently known to prevent vitiligo.

Vitrectomy

Definition

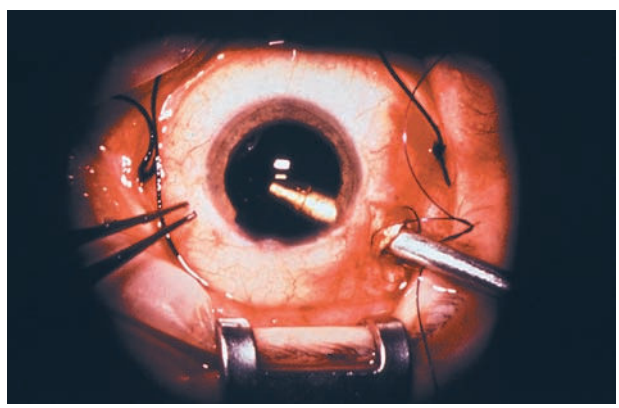
Vitrectomy is the surgical removal of the vitreous (transparent gel that fills the eye from the iris to the retina).

Purpose

The bulk of the contents of the eyeball is a clear jelly-like substance that is susceptible to several afflictions that impair vision by damaging its transparency.

- Infections
- Injuries
- Bleeding, particularly from diabetic retinopathy
- Blood vessels growing into the vitreous, again due to diabetes

The retina is the light-sensitive membrane that receives images and transmits them to the brain. It covers the inside of the back of the eye. On occasion the retina will fall into the vitreous, a condition called **retinal detachment**. This may be due to disease in the vitreous that pulls the retina inward, small tears in the retina that allow liquid to seep behind it and push it



Vitrectomy is a surgical procedure in which the vitreous, the transparent gel that fills the eye from the iris to the retina, is removed. During this procedure, the surgeon penetrates the eyeball with a tiny instrument (shown above). *(Photo Researchers, Inc.)*

KEY TERMS

Computed tomography (CT scan)—Computerized method of creating images of internal organs using x rays.

Diabetic retinopathy—Disease that damages the blood vessels in the back of the eye caused by diabetes mellitus.

Endophthalmitis—Inflammation of the eyeball.

Iatrogenic—Inadvertently caused by medical treatment.

Magnetic resonance imaging (MRI)—Computerized method of creating images of internal organs using magnetic fields.

Saline—A salt solution equivalent to that in the body—0.9% salt in water.

forward, or injury to the eye that simply breaks the retina loose. It may be necessary to remove the vitreous in order to replace the retina and restore vision.

Description

Using instruments suited for microscopic surgery, the ophthalmologist (eye surgeon) penetrates the eyeball, aspirates the vitreous, and replaces it with saline. The saline replaces the vitreous at a constant pressure in order to keep the eye from collapsing. Once the saline is in place, both eyes are patched. The procedure takes two to three hours to complete.

Preparation

Because this is a major operation on the eye, the surgeon will perform a very extensive evaluation of both eyes. After looking inside with a variety of lenses, a CT, MRI, or **ultrasound** study may be needed. Immediately prior to the vitrectomy, the pupils will be dilated.

Aftercare

Eye drops and **antibiotics** are administered, and eye rest is advised until healing is completed.

Risks

Risks associated with vitrectomy are retinal detachment, bleeding, iatrogenic (medically caused) **cataracts**, and endophthalmitis (inflammation of the eyeball).

Normal results

Vision is restored to useful levels in two-thirds of patients.

Vocal cord nodules and polyps

Definition

Vocal cord nodules and polyps are noncancerous growths on the vocal cords that affect the voice.

Description

The vocal cords, located in the voice box in the middle of the neck, are two tough, fibrous bands that vibrate to produce sound. They are covered with a layer of tissue that is similar to skin. With use, this layer thickens. With heavy use, the thickening may localize, producing a nodule. Unlike skin, heavy usage over a short time may also produce polyps. A polyp is a soft, smooth lump containing mostly blood and blood vessels. A nodule is similar to a polyp, but tends to be firmer.

Causes and symptoms

Chronic infections caused by **allergies** and inhalation of irritants, such as cigarette smoke, may produce these lesions, but extensive use of the voice is the most common cause of vocal nodules and polyps. Nodules and polyps are more common in male children, female adolescents, and female adults. This may be due in part to the faster speed at which the cords vibrate to produce higher-pitched voices.

Voice alterations are most apparent in singers, who may notice the higher registers are the first to change. Hoarseness causes others to seek medical attention.

Diagnosis

The head and neck surgeon (otorhinolaryngologist) must see the vocal cords to diagnose these lesions. It is also important to confirm that there are not other problems instead of or in addition to these benign

WWW.BOOKBAZ.IR

KEY TERMS

Laryngitis—Inflammation of the larynx (voice box).

Lesion—A wound or injury.

Otorhinolaryngologist—A physician specializing in ear, nose, and throat diseases. Also known as otolaryngologist.

lumps. Other causes of hoarseness include throat cancers, **vocal cord paralysis**, and simple **laryngitis**. The cords can usually be seen using a mirror placed at the back of the tongue. More elaborate scopes, including a videostroboscope, allow better views while the cords are producing sounds.

A biopsy of a nodule or polyp will ensure they are not cancerous.

Treatment

Nodules usually only require voice therapy; less than 5% of nodules require surgery. Small polyps can be treated with voice therapy, but typically they are surgically removed.

Prognosis

Continued overuse of the voice will cause these lesions to regrow.

Prevention

Careful use of the voice will prevent most vocal cord nodules and polyps. Avoiding inhaled irritants may also prevent nodules and polyps from forming.

Vocal cord paralysis

Definition

Vocal cord **paralysis** is the inability to move the vocal cords and the resulting loss of vocal cord function.

Description

The vocal cords are a pair of tough, fibrous bands that lie across the air column in the middle of the voice box. They assist three functions: breathing, swallowing, and speaking. When vocal cords vibrate, they produce sound, allowing us to speak. Vocal cords temporarily stop breathing to aid coughing and for expelling **foreign objects**. During swallowing, the vocal cords shut the airway so that food is not inhaled. When vocal cords are paralyzed, all three functions are affected.

The relaxed position of the vocal cords is halfway open. There is one set of muscles that closes them all the way and one set that opens them. Each set of muscles is controlled by a different nerve. Each nerve comes from a different direction—one from above and one from below (the recurrent laryngeal nerve). Vocal cords can either be partially paralyzed on one side or completely paralyzed on both sides.

Causes and symptoms

Vocal cord paralysis can result from injury, tumors, or surgery in the neck and upper chest. Brain tumors and **stroke** can also affect the nerves. Infectious diseases that damage nerves—like whooping **cough**, **tetanus** and polio—can also cause vocal cord paralysis. Vocal cord paralysis can also appear as a congenital defect. If congenital, the most frequent cause is a brain defect, which can often be effectively treated.

The most dangerous form of vocal cord paralysis is one that affects the opening function, controlled by the recurrent laryngeal nerve. If both vocal cords are paralyzed, breathing stops or becomes very labored. Fortunately, injury during **trauma** or surgery often involves only one side, but the congenital causes can damage both sides.

Vocal cord paralysis produces several symptoms.

- The voice is always affected; at best it is breathy and weak. At worst, it is not there at all. In infants, the cry can be weak. Older children will suppress laughing and coughing because it is hard to do.
- Swallowing may be hindered so that food ends up in the airway, causing violent coughing and often leading to pneumonia.
- Breathing is obstructed on aspiration, producing a condition known as stridor. Closing the airway while breathing in produces creaking noises in the throat and changes the shape of the chest. The breast bone is drawn inward, much more visibly in the flexible chest of a small child.

KEY TERMS

Computed tomography (CT scan)—Computerized use of x rays to create images of internal organs.

Laryngoscope—A diagnostic instrument that is used to examine the interior of the larynx.

Magnetic resonance imaging (MRI)—Computerized use of magnetic fields and radio-frequency signals to create images of internal organs.

Recurrent laryngeal nerve—One of two offshoots of the vagus nerve that connect to the larynx. It is located below the larynx.

Stridor—A raspy sound that occurs during respiration when the airways are blocked.

Tracheostomy—Surgical opening in the neck to the trachea to aid respiration.

Voice box—The larynx.

Diagnosis

The voice box must be observed during breathing to characterize the problem. A viewing instrument called a laryngoscope, either flexible or rigid, is passed through the nose or throat until the cords becomes visible. The motion of each cord can then be seen, and other problems in the area identified.

X rays, CT, or MRI scans of the skull may be done if a brain disorder is suspected.

Treatment

An adequate airway is immediately necessary, usually secured with an endotracheal tube in the windpipe. If a cure cannot be achieved, a permanent breathing hole (tracheostomy) is cut in the neck. Brain problems that are relieved within 24 hours usually allow the cords to regain their function. Care must be taken to assure that swallowing takes place normally.

Alternatives

Vocal cord paralysis can be addressed with constitutional homeopathy. This will work with the whole person, not just the symptoms, to help bring about healing. Botanical medicine and deep tissue massage to the area can also bring some resolution, although it may not be long term.

Volkmann's contracture

Definition

Volkmann's contracture, also known as Volkmann's ischemic contracture, is a permanent flexion contracture of the hand at the wrist, caused by a shortening of the forearm muscles as a result of injury. The patient's hand and fingers are curled into a clawlike shape. The condition is named for Richard von Volkmann (1830–1889), a German surgeon who first described it in 1881.

Description

Volkmann's contracture is sometimes described as a form of **compartment syndrome**, a disorder that results from an increase in pressure in a body compartment, which is a section within the human body containing muscles and nerves and surrounded by fascia. There are two compartments in the upper arm and four in the forearm. Volkmann's contracture can be defined as forearm compartment syndrome. Volkmann himself thought that the contracture resulted from insufficient arterial blood flow to the forearm caused by overly tight bandages. In 1909, a later researcher named Thomas reviewed the 112 cases of the contracture that had been published up to that time and found that the majority were caused by factures of the humerus (the long bone in the upper arm) above the elbow, although he noted that tight bandages and arterial blockage could also cause the contracture. During World War II, combat surgeons observed cases of Volkmann's contracture among infantrymen struck by high-velocity bullets in the upper arm, but the importance of emergency **fasciotomy** in preventing Volkmann's contracture was not fully understood until the Vietnam War in 1967.

WWW.BOOKBAZ.IR

(Illustration by Electronic Illustrators Group. © Cengage Learning®.)

Orthopedic surgeons classify Volkmann's contracture as mild, moderate, or severe:

- Mild: The patient has a flexion contracture of the hand (the hand is bent inward toward the wrist) that affects two or three fingers. There is little or no loss of sensation in the fingers.
- Moderate: All fingers are flexed, with the thumb pointed inward toward the palm. There is usually a loss of sensation in the hand.
- Severe: The muscles of the forearm as well as those of the hand are affected. A severe Volkmann's contracture is a serious limitation for the patient, particularly if the dominant hand is affected.

Risk factors

Risk factors for Volkmann's contracture include any activity or injury that can result in fracture of the humerus bone above the elbow or fracture of the forearm bones, such as an intentional blow to the upper arm, sports injury, high-velocity gunshot wound, motor vehicle accident, or similar traumatic injuries. Males appear to be at higher risk than females because of lifestyle factors.

Demographics

Volkmann's contracture occurs most often in children, although it has also been observed in combat veterans. It is rare in the general population, with an incidence of about 0.5%; most discussions of Volkmann's contracture in the medical literature are of isolated cases rather than large series. As far as is known, the disorder occurs with equal frequency worldwide and in all racial and ethnic groups.

Causes and symptoms

The basic cause of Volkmann's contracture is the shortening of the forearm muscles and subsequent deformity of the fingers due to compartment syndrome. When the fluid pressure inside a body compartment (such as the forearm) rises above a certain level (usually given as 30 mm Hg), it closes the blood vessels that supply the nerves and muscles in that compartment, causing a condition called ischemia. Deprived of the oxygen and nutrients needed to maintain cellular function, and unable to return the waste products of cellular metabolism through the veins, the ischemic tissues begin to die. Muscle and nerve deterioration occurs if treatment is not begun within a few hours after the injury. Muscles will show functional impairment after 2–4 hours of ischemia and irreversible functional loss after 4–12 hours, while nerve tissue shows abnormal function after 30 minutes of ischemia, with irreversible functional loss after 12–24 hours.

In the specific case of Volkmann's contracture, a displaced fracture of the humerus above the elbow leads to pressure on the brachial artery, which carries oxygenated blood to the nerves and muscles of the forearm, the wrist, and the fingers. If the occlusion (blockage) of this artery is not relieved by a surgical procedure (fasciotomy) to lower the fluid pressure that is closing the artery and the nearby veins, the ischemic muscles in the forearm, wrist, and fingers will contract as waste products accumulate in the tissues and the tissue cells begin to die. Volkmann's contracture can also result from **fractures** of the forearm bones (the radius and the ulna), leading to heavy bleeding from the blood vessels in the forearm and consequent compartment syndrome.

Pain is usually the most prominent symptom.

Diagnosis

The initial diagnosis is made on the basis of the location of the injury to the arm and the so-called "5 Ps" associated with compartment syndrome:

- Pain: This is the earliest symptom, and is intensified if the examining physician attempts to stretch the affected muscles or palpate the area.
- Pallor: The skin over the forearm, wrist, and hand will be pale and have a "bleached" appearance. The fingers may be bluish in color and cold to the touch.

- Pulselessness: The radial (wrist) pulse will be undetectable.
- Paresthesias: The patient will experience tingling or pins-and-needles sensations in the hand and forearm.
- Paralysis: The patient will be unable to move the affected limb.The doctor may also notice that the skin of the patient's forearm feels unusually firm to the touch.

X rays of the upper arm and forearm are then taken to confirm the diagnosis of a bone fracture, to pinpoint its location, and to determine whether the fractured bone is displaced. Volkmann's contracture is typically associated with a displaced fracture of the humerus; if the bone has not been displaced, a contracture is less likely. Fractures of the forearm bones, however, must also be identified to prevent a contracture.

Treatment

Treatment of a fractured humerus or either of the two bones in the forearm (the radius and the ulna) must be given correctly as well as promptly, as some cases of Volkmann's contracture have resulted from overly tight bandages or improperly applied casts or tourniquets that cut off the circulation to the forearm. If the injury is fresh, setting the broken bone(s) in proper alignment without surgical exposure of the fracture (known as a closed reduction) and holding the fragments in position with a cast may avoid the need to treat a contracture surgically. The patient can be given NSAIDs or opioid pain medications for pain control during the procedure.

If the injury has not been treated for several hours and the first symptoms of compartment syndrome are beginning to appear, the standard treatment is decompression of the compartment. Decompression usually involves an emergency fasciotomy, a surgical procedure in which the doctor makes an incision through the fascia, the layer of connective tissue around the muscles and nerves in the compartment. Any casts or bandages that were applied to the injury are removed before the fasciotomy. The patient's arm is supported at heart level rather than elevated, as keeping the limb at the level of the heart encourages blood flow to the affected compartment. The surgeon is careful to decompress the medial nerve along its full length to maintain sensation in the hand and fingers. The patient may also be given hyperbaric oxygen treatment to increase the amount of oxygen in the ischemic tissues.

If the contracture has already occurred, treatment depends on its severity:

- Mild: Mild contractures are treated with physical therapy to restore strength, function, and range of motion in the affected hand and fingers. Surgical lengthening of the tendons in the hand is also done.
- Moderate: Moderate contractures typically require the transfer of tendons from another part of the body to restore function as well as physical therapy and rehabilitation. If a tendon transfer cannot be performed, a free muscle transfer may be used instead.
- Severe: A severe contracture requires debridement (surgical removal) of damaged muscle along with the surgical release of scar tissue. Tendon transfers are performed at a later date, along with free muscle transplantation to restore function to the hand.

KEY TERMS

Compartment—A section within the human body that contains muscles and nerves, and is surrounded by fascia.

Compartment syndrome—Increased pressure, commonly following surgery or injury, within one of the body's compartments. It may be either acute or chronic. Volkmann's contracture is associated with forearm compartment syndrome.

Contracture—A permanent shortening of a muscle or joint.

Fascia—A layer of smooth connective tissue that surrounds and covers muscles, muscle groups, blood vessels, and nerves, binding these structures together and separating the various compartments within the body.

Fasciotomy—A surgical procedure in which fascia is cut to relieve pressure in a body compartment in order to restore normal blood circulation and prevent the loss of tissue or muscle.

Flexion—A bending motion or position that decreases the angle between two body parts. Volkmann's contracture is a flexion contracture of the hand.

Humerus—The long bone in the upper arm that runs from the shoulder to the elbow.

Ischemia—A reduction in or restriction of blood to tissues, depriving them of the oxygen and glucose needed for adequate function.

Radius—The shorter and smaller of the two long bones in the forearm.

Ulna—The longer and heavier of the two long bones in the forearm.

WWW.BOOKBAZ.IR

Prognosis

Prognosis depends on the promptness of treatment for a fractured humerus or forearm bones, and the skill of the initial treatment provided. Nerve injuries occur in 7% of cases of Volkmann's contracture but sometimes improve with careful management. If treatment is performed in time, motor function in the affected hand returns in 7–12 weeks. Sensation, however, may take as long as 6 months to return. The complications of fasciotomy performed to prevent Volkmann's contracture include **itching** at the incision site, formation of scar tissue, dry or scaly skin, altered sensation around the margins of the incision, recurrent ulceration, and recurrent pain.

Prevention

Prevention of Volkmann's contracture depends primarily on prompt and competent treatment of bone fractures in the upper arm or forearm, although measures to prevent accidental or sports-related injuries to the arm are also beneficial.

Vomiting

Definition

Vomiting is the forceful emptying or throwing up of a large portion of the stomach contents through the mouth. It can include the complete inability to hold fluids or food in the stomach. Vomiting is often accompanied or preceded by abdominal discomfort and nausea. **Nausea and vomiting** are also called emesis.

Demographics

Vomiting is very common, especially in the early years of life. Contagious rotaviruses are one of the most common causes of vomiting in infants and young children. Fortunately, rotavirus infection has

become less prevalent in the United States since the introduction of a vaccine.

Although vomiting can stem from a variety of causes at any stage of life, **cyclic vomiting syndrome** (CVS) most often affects children. As many as one in 50 children may experience CVS, which most often begins between the ages of three and seven years. It was once thought to primarily affect girls, but CVS is now believed to be equally common in boys.

Description

Vomiting is a reflex reaction in which the abdominal muscles and diaphragm vigorously contract while the stomach is relaxed. The vomiting center in the brain triggers this reaction when it is stimulated by factors such as:

- nerve signals from the stomach and intestine that indicate irritation or swelling of the gastrointestinal tract
- chemicals in the blood, including various drugs
- psychological stimuli, such as particular sights or smells
- signals from the middle ear, as with motion sickness

Spitting up by infants, especially during the first year of life, is not considered vomiting. Spitting up is the occasional movement of small amounts of breast milk or formula from the stomach, through the esophagus, and out of the mouth, often accompanied by a burp.

Risk factors

Various medical conditions can cause vomiting. Most vomiting in children is not due to any particular risk factors. Children with CVS often have a family history of migraine and may themselves develop migraine headaches as they get older.

Causes and symptoms

Vomiting in children after the first few months of life is most often caused by **gastroenteritis** or **gastritis**. This is usually a viral infection of the gastrointestinal tract, often caused by a rotavirus. It also can be caused by **noroviruses**, enteroviruses, or adenoviruses, or bacteria or parasites. Sometimes called stomach flu, gastroenteritis usually starts with vomiting, followed by **diarrhea** within 12–24 hours. Other symptoms may include nausea, **fever**, and abdominal **pain**. Gastroenteritis is usually contagious.

Other causes of vomiting include:

- infections other than gastroenteritis, including infections of the respiratory system, urinary tract, middle ear (otitis), or membranes surrounding the brain and spinal cord (meningitis)
- a problem with infant formula
- foods that are hard to digest, such as excess sugar
- food poisoning from bacteria in undercooked meat or fish or from improperly refrigerated foods, such as *Staphylococcus* toxin in egg salad or *Bacillus cereus* toxin in rice dishes
- motion sickness
- migraine headaches
- medications, including cancer chemotherapy
- morning sickness during pregnancy

There are several serious causes of vomiting in infants:

- Pyloric stenosis is a thickening of the muscle at the end of the stomach that prevents food from entering the intestines. It causes persistent forceful vomiting of large amounts of fluid or formula within about 15–30 minutes after feeding. It is most common in infants between the ages of two weeks and four months.
- Spitting up that gradually increases during the first few weeks to months of life may indicate gastroesophageal reflux disease (GERD). GERD occurs when the muscles at the lower end of the esophagus are overly relaxed, enabling the stomach contents to back up.
- Intussusception is an intestinal obstruction in which a portion of the bowel slides into an adjacent portion. It is most common between 5 and 10 months of age and is indicated by vomiting all liquids, red-colored diarrhea, and uncontrollable crying while pulling the knees to the chest.
- Appendicitis may be suggested by vomiting that persists for more than 24 hours without diarrhea.

CVS is characterized by episodes of severe nausea, gagging, and vomiting that have no known cause and last for hours or one or two days. Vomiting may occur as often as 12 times in an hour. Episodes generally begin at about the same time of day—usually late at night or upon waking in the morning. Each episode has similar symptoms and intensity levels and lasts for about the same length of time. Episodes of CVS in children are often triggered by excitement or **stress**. Children have about 12 episodes per year.

At the start of an illness that causes vomiting, especially **food poisoning**, it is common for children to vomit everything in their stomachs for three or four hours, followed by mild or moderate vomiting. Excessive vomiting, especially in combination with diarrhea, can cause dehydration—the excessive loss of body fluids. Although **dehydration** can occur at any age,

WWW.BOOKBAZ.IR

KEY TERMS

Appendicitis—Inflammation of the appendix—a narrow blind tube in the lower right abdomen.

Cyclic vomiting syndrome (CVS)—Episodes of severe nausea, gagging, and vomiting in children that last for hours or a day or two, repeat at regular intervals, and have no known cause.

Dehydration—Abnormal depletion of bodily fluids.

Diarrhea—Abnormally frequent bowel movements with fluid stools.

Gastroenteritis—Also called gastritis or stomach flu; inflammation of the lining of the stomach and intestines.

Gastroesophageal reflux disease (GERD)—Recurrent heartburn or acid indigestion caused by leakage of the stomach contents into the esophagus.

Motion sickness—Also called kinetosis; nausea and possibly vomiting induced by motion, such as travel by car, boat, or plane.

Nausea—Stomach distress characterized by a distaste for food and the urge to vomit.

Oral rehydration solution (ORS)—Oral electrolyte maintenance solution; a balanced salt solution, containing some sugar, that replaces fluid and salts lost through vomiting and diarrhea.

Rotavirus—Any virus of the genus *Rotavirus,* some of which cause gastroenteritis.

young children can become dehydrated very quickly. In general, a child's risk for dehydration is:

- mild, if vomiting one to three times per day
- moderate, if vomiting 4–10 times per day
- severe, if a baby vomits continuously for 6–12 hours or a child aged two or older for 12–24 hours, especially if vomiting is accompanied by watery stool

Signs and symptoms of dehydration include:

- thirst—indicated by infant crying, irritability, and eagerly drinking
- dry mouth
- infrequent urination—less than six wet diapers per day or eight hours or more without urinating
- dark urine
- irritability
- poor appetite
- weight loss
- lack of tears when crying
- sunken soft spots on top of the head in babies under 18 months of age
- loss of springiness or elasticity of the skin
- sleepiness
- inability to drink adequate fluid

Diagnosis

Examination

Medical consultation and a **physical examination** are required if a child is vomiting and:

- may have been poisoned
- cannot retain any clear liquids
- is less than six months old
- is older than six months and has a fever above 101.4°F (38.5°C)
- has been vomiting for more than eight hours or is vomiting with increasing force
- has blood in the stool
- has blood or bile (greenish liquid) in the vomit
- has a headache and stiff neck
- is lethargic, listless, or unusually sleepy
- has severe abdominal pain or abdominal pain for more than two hours
- is very irritable
- is having convulsions
- has signs or symptoms of dehydration

Tests

Blood and/or urine tests may be performed. If a bacterial infection is suspected, a stool sample may be cultured to identify the bacteria and its susceptibility to **antibiotics**.

Procedures

If the physician suspects that the vomiting is a symptom of a serious problem in the gastrointestinal tract, x rays or other imaging procedures may be performed.

Treatment

Traditional

Vomiting is most often caused by a virus and resolves without treatment. Severe diarrhea may require the administration of intravenous (IV) fluids in a hospital. Serious underlying causes of vomiting, such as **pyloric stenosis** or **appendicitis**, may require surgery.

Drugs

Oral rehydration solution (ORS) may be required to replace fluids and nutrients lost through vomiting and diarrhea. ORS is safe for babies and older children and is readily available in grocery stores and pharmacies. It comes in various forms, including liquid, a powder to be mixed with water, and frozen popsicles. Brands include Pedialyte, Ricelyte, Rehydralyte, and the World Health Organization's Oral Rehydration Solution (WHO-ORS).

Over-the-counter and prescription remedies should not be used to treat vomiting unless specifically prescribed by a physician:

- Antiemetic drugs, such as bismuth subsalicylate (Kaopectate, Pepto-Bismol), can help relieve nausea and vomiting, but should not be given to children aged 12 or younger, or to children under 18 who may have the flu or chicken pox, because of the risk of Reye's syndrome.
- Antibiotics may be prescribed for a bacterial infection that is causing vomiting.
- Antihistamines can help prevent nausea and vomiting from motion sickness, especially if they are taken before the problem develops. They are believed to dampen the perception of motion by the middle ear and/or block nerve signals to the vomiting center in the brain. Motion sickness drugs include dimenhydrinate (Dramamine) and meclizine hydrochloride (Dramamine Less Drowsy).

Alternatives

Ginger (*Zingiber officinale*) is used in Asian medicine to treat stomachaches, nausea, and diarrhea. Studies indicate that short-term use of ginger can safely treat nausea and vomiting from morning sickness and may possibly be effective for nausea from **motion sickness**, **chemotherapy**, or surgery. Ginger is available in various forms, including fresh or dried root, tablets, capsules, liquid extracts or tinctures, and teas. Ginger extract is included in many digestive, anti-nausea, cold, and flu supplements sold in the United States.

Home remedies

The correct balance of salts (electrolytes) is very important for infants. Breast milk contains the proper fluids and electrolytes. Infants who are exclusively breastfed and vomit their entire feeding more than once should be breastfed for a total of 5–10 minutes every two hours, returning to normal **breastfeeding** after vomiting has ceased for eight hours. Babies who are not exclusively breastfed should be treated with ORS—unflavored for infants under six months. Older babies can be given flavored ORS, or it can be flavored with 0.5 tsp (3 mL) of non-acidic juice. Frozen ORS pops also can be given to older babies. ORS can be made by mixing 8 tsp (48 mL) of sugar and 1 tsp (6 mL) of salt in a quart (4 cups, 0.9 L) of water. Adding a cup of orange juice to the mix or feeding the child a banana will supply needed potassium.

Vomiting infants and young children should be kept lying on their stomachs or sides as much as possible to reduce the risk of inhaling vomit into the upper airways or lungs.

Vomiting infants under one year:

- should not be given plain water unless the physician has specified an amount
- should be offered 2–3 tablespoons or up to 0.5 oz (15 mL) of ORS every 15–20 minutes with a spoon or oral syringe
- should be given an increasing amount of ORS once the solution is kept down for more than two hours, slowly increasing it over a day to the amount that is normally taken in one feeding, such as 4 oz (120 mL)
- should not be given more solution at one time than they would normally be fed, so as not to cause more vomiting
- should be reintroduced to formula slowly after at least eight hours without vomiting, beginning with frequent feedings of 0.5–1 oz (15–30 mL) for a young infant and 1–2 oz (30–60 mL) for an infant over six months
- can be slowly returned to their normal baby cereal or soft, bland foods such as bananas, crackers, or other mild baby food
- should be slowly returned to normal feedings after not vomiting for 24 hours

Vomiting children over one year of age should be given small amounts (2 teaspoons to 2 tablespoons, up to 1 oz or 30 mL) of clear fluids every 15 minutes. Appropriate fluids include ice chips, water, ORS, or frozen ORS pops. They should not be given milk or milk products. If the child vomits again, 2 tsp (5 mL) of fluid should be given. Small amounts every few minutes may stay down better than larger amounts. Children can also be given clear soups or sodas or juice mixed with water. They should not be given dark sodas, which are usually high in sugar and can irritate the stomach. After six to eight hours without vomiting, mild, bland foods can be slowly reintroduced. Appropriate foods include saltine crackers, bread, toast, broths, mild soups, mashed potatoes, or rice. The child should not be forced to eat. After 24 hours without vomiting, a normal diet can be gradually

WWW.BOOKBAZ.IR

resumed. Milk products should not be given for two to three days.

GERD can usually be controlled by:

- not overfeeding
- feeding smaller amounts more frequently
- burping frequently
- thickening milk with small amounts of baby cereal, as directed by the pediatrician
- placing the infant in a safe, quiet, upright position for at least 30 minutes after feeding

Prognosis

Children usually recover from vomiting quickly without treatment. Most children with CVS outgrow it as teenagers, although they are at increased risk for migraines as adults.

Prevention

Measures to help prevent vomiting include:

- thorough, frequent hand washing, especially before cooking and eating, after handling raw meat, and after using the toilet, to help prevent infection and food poisoning
- a healthy diet
- avoiding close contact with someone with gastroenteritis
- vaccination against rotavirus

Von Willebrand disease

Definition

Von Willebrand disease is caused by a deficiency or an abnormality in a protein called von Willebrand factor and is characterized by prolonged bleeding.

Description

The Finnish physician Erik von Willebrand was the first to describe von Willebrand disease (VWD). In 1926 Dr. von Willebrand noticed that many male and female members of a large family from the Aland Islands had increased bruising (bleeding into the skin) and prolonged episodes of bleeding. The severity of the bleeding varied between family members, ranged from mild to severe, and typically involved the mouth, nose, genital and urinary tracts, and occasionally the intestinal tract. Excessive bleeding during the menstrual period (menorrhagia) was also experienced by some of the women in this family. What

differentiated this bleeding disorder from classical **hemophilia** was that it appeared not to be associated with muscle and joint bleeding and affected people of either sex rather than just men. Dr. von Willebrand named this disorder *hereditary pseudohemophilia*.

Pseudohemophilia, or von Willebrand disease (VWD) as it is now called, occurs when the body does not produce enough of a protein called von Willebrand factor (VWF) or produces abnormal VWF. VWF is involved in the process of blood clotting (coagulation). Blood clotting is necessary to heal an injury to a blood vessel. When a blood vessel is injured, VWF enables blood cells called platelets to bind to the injured area and form a temporary plug to seal the hole and stop the bleeding. VWF is secreted by platelets and by the cells that line the inner wall of the blood vessels (endothelial cells). The platelets release other chemicals, called factors, in response to a blood vessel injury that are involved in forming a strong permanent clot. VWF binds to and stabilizes factor VIII, one of the factors involved in forming the permanent clot.

A deficiency or abnormality in VWF can interfere with the formation of the temporary platelet plug and also affect the normal survival of factor VIII, which can indirectly interfere with the production of the permanent clot. Individuals with VWD, therefore, have difficulty in forming **blood clots** and as a result they may bleed for longer periods of time. In most cases the bleeding is due to an obvious injury, although it can sometimes occur spontaneously.

VWD is classified into three basic types: type 1, type 2, and type 3. The definitions of each type are based on the amount and type of VWF that is produced. Type 1 is the most common and mildest form and results when the body produces slightly decreased amounts of typically normal VWF. Type 2 can be classified into four subtypes (IIA,IIB,IIM, and IIN) and results when the body produces an abnormal type of VWF. Type 3 is the rarest and most severe form and results when the body does not produce any detectable amount of VWF.

Approximately 1 out of 100 people are affected with VWD, making it the most common inherited bleeding disorder (hemophilia). VWD affects people of all ethnic backgrounds. Approximately 70–80% of people with VWD have type 1 and close to 20–30% have type 2. Type 3 is very rare and occurs in fewer than 1% of people with VWD.

Causes and symptoms

The genetics of VWD are complex and involve a gene that produces VWF and is found on the short arm of chromosome 12. Since humans inherit two of each type of chromosome, they inherit two VWF genes. There are different types of changes (mutations) in the VWF gene that can affect the production of VWF. Some types of changes can cause the VWF gene to produce decreased amounts of normal VWF, while other changes can cause the gene to produce abnormal VWF. Most of the gene changes are significant enough that a change in only one VWF gene is sufficient to cause VWD. Some gene mutations cause VWD only if both genes are changed, which often leads to more severe symptoms.

Type 1 VWD is called an autosomal dominant condition since it is caused by a change in only one VWF gene. Since type 1 VWD results in only a slight decrease in the amount of VWF produced, the symptoms are often mild and even non-existent in some patients. Most cases of Type 2 VWD are autosomal dominant since they are caused by a change in only one VWF gene that results in the production of an abnormal protein. An autosomal dominant form of VWD can be inherited from either parent or can occur spontaneously in the embryo that is formed when the egg and sperm cells come together during fertilization.

Some cases of type 2 VWD and all cases of type 3 VWD are autosomal recessive since they are caused by changes in both VWF genes. Individuals with an autosomal recessive form of VWD have inherited a changed gene from their mother and a changed gene from their father. Parents who have a child with an autosomal recessive form of VWD are called carriers, since they each possess one changed VWF gene and one unchanged VWF gene. Many carriers for the autosomal recessive forms of type 2 VWD and type 3 VWD do not have any symptoms, although some people with type 3 VWD are born to parents who have type 1 VWD and may have symptoms. Each child born to parents who are both carriers for VWD has a 25% chance of having VWD, a 50% chance of being a carrier, and a 25% chance of being neither a carrier nor affected with VWD disease. Individuals with an autosomal dominant form of VWD have a 50% chance of passing the changed gene on to their children who may or may not have symptoms.

VWD is usually a relatively mild disorder characterized by easy bruising, recurrent nosebleeds, heavy menstrual periods, and extended bleeding after surgeries and invasive dental work. There is a great deal of variability in the severity of symptoms, which can range from clinically insignificant to life-threatening. Even people within the same family who are affected with the same type of VWD may exhibit different symptoms. Individuals with VWD may exhibit a range of symptoms over the course of their lifetime and may experience an improvement in symptoms with age. The severity of

WWW.BOOKBAZ.IR

the disease is partially related to the amount and type of VWF that the body produces, but is also influenced by other genetic and non-genetic factors.

Type 1

Type 1, the mildest form of VWD, is usually associated with easy bruising, recurrent nosebleeds, heavy menstrual periods, and prolonged bleeding after surgeries and invasive work. Many people with type 1 VWD do not have any noticeable symptoms or only have prolonged bleeding after surgery or significant **trauma**. The amount of VWF produced by the body increases during **pregnancy**, so prolonged bleeding during delivery is uncommon in people with type 1 VWD.

Type 2

People with type 2 VWD usually have symptoms from early childhood and symptoms may even be present at birth. They usually experience prolonged bleeding from cuts, easy bruising, nose bleeds, skin hematomas, and prolonged bleeding from the gums following teeth extraction and minor trauma. More than 50% of women with type 2 VWD experience heavy periods that may require a blood **transfusion**. Gastrointestinal bleeding is rare but can be life-threatening. Some women with type 2 VWD exhibit prolonged bleeding during delivery.

Type 3

Type 3 VWD can be quite severe and is associated with bruising and bleeding from the mouth and nose, as well as intestinal, genital, and urinary tracts. Type 3 is also associated with spontaneous bleeding into the muscles and joints, which can result in joint deformities. Some women with type 3 VWD experience prolonged bleeding during delivery.

Diagnosis

Diagnostic testing

Many people with VWD have mild symptoms or symptoms that can be confused with other bleeding disorders, making it difficult to diagnose VWD on the basis of clinical symptoms. VWD should be suspected in any person with a normal number of platelets in their blood and bleeding from such mucous membranes as the nose, gums, and gastrointestinal tract. Testing for an individual with suspected VWD often includes the measurement of:

- how long it takes for the bleeding to stop after a tiny cut is made in the skin (the bleeding time)
- the amount of VWF (VWF antigen measurement)
- the activity of VWF (ristocetin co-factor activity)
- the amount of factor VIII (factor VIII antigen measurement)
- activity of factor VIII

Many doctors routinely screen women with menorrhagia for VWD, as heavy menstrual bleeding is the most common symptom of the disorder in females.

People with type 1 VWD usually have an increased **bleeding time**, but they may have an intermittently normal bleeding time. They also have a decreased amount of VWF, and decreased VWF activity and usually have slightly decreased factor VIII levels and activity. People with type 2 VWD have a prolonged bleeding time, decreased activity of VWF and may have decreased amounts of VWF and factor VIII, and may have decreased factor VIII activity. Type 3 individuals have undetectable amounts of VWF, negligible VWF activity, factor VIII levels of less than 5–10%, and significantly reduced factor VIII activity. The activity of VWF is reduced for all types of VWD, making it the most sensitive means of identifying all three types of VWD. Patients with borderline results should be tested two to three times over a three month period.

Once a patient is diagnosed with VWD, further testing such as VWF multimer analysis and ristocetin-induced platelet aggregation (RIPA) may need to be performed to determine the subtype. Multimer analysis evaluates the structure of the VWF, and RIPA measures how much ristocetin is required to cause the clumping of platelets in a blood sample. The VWF multimer analysis is able to differentiate people with a structurally normal VWF (type 1) from people with a structurally abnormal VWF (type 2) and is often able to identify the subtype of patients with type 2 VWD. People with type 1 VWD usually have normal to decreased RIPA concentrations. Depending on the subtype, patients with type 2 VWD either have increased or decreased RIPA. RIPA is usually absent and the multimer analysis shows undetectable VWF in people with type 3 VWD.

In some cases DNA testing can be a valuable adjunct to biochemical testing. The detection of gene alteration(s) can confirm a diagnosis and can determine the type and subtype of VWD. It can also help to facilitate prenatal testing and testing of other family members. Unfortunately, many people with VWD possess DNA changes that are not detectable through DNA testing. A person who has a mother, father, or sibling diagnosed with VWD should undergo biochemical testing for VWD. If the relative with VWD possesses a detectable gene change, then DNA testing should also be considered.

KEY TERMS

Amniocentesis—A procedure performed at 16-18 weeks of pregnancy in which a needle is inserted through a woman's abdomen into her uterus to draw out a small sample of the amniotic fluid from around the baby. Either the fluid itself or cells from the fluid can be used for a variety of tests to obtain information about genetic disorders and other medical conditions in the fetus.

Autosomal dominant—A pattern of genetic inheritance where only one abnormal gene is needed to display the trait or disease.

Autosomal recessive—A pattern of genetic inheritance where two abnormal genes are needed to display the trait or disease.

Biochemical testing—Measuring the amount or activity of a particular enzyme or protein in a sample of blood or urine or other tissue from the body.

Carrier—A person who possesses a gene for an abnormal trait without showing signs of the disorder. The person may pass the abnormal gene on to offspring.

Chorionic villus sampling (CVS)—A procedure used for prenatal diagnosis at 10–12 weeks gestation. Under ultrasound guidance a needle is inserted either through the mother's vagina or abdominal wall and a sample of cells is collected from around the early embryo. These cells are then tested for chromosome abnormalities or other genetic diseases.

Chromosome—A microscopic thread-like structure found within each cell of the body that consists of a complex of proteins and DNA. Humans have 46 chromosomes arranged into 23 pairs. Changes in either the total number of chromosomes or their shape and size (structure) may lead to physical or mental abnormalities.

Deoxyribonucleic acid (DNA)—The genetic material in cells that holds the inherited instructions for growth, development, and cellular functioning.

Desmopressin (DDAVP)—A drug used in the treatment of von Willebrand's disease.

Diagnostic testing—Testing performed to determine if someone is affected with a particular disease.

DNA testing—Analysis of DNA (the genetic component of cells) in order to determine changes in genes that may indicate a specific disorder.

Endothelial cells—The cells lining the inner walls of the blood vessels.

Factor VIII—A protein involved in blood clotting that requires VWF for stability and long-term survival in the bloodstream.

Gene—A building block of inheritance, which contains the instructions for the production of a particular protein, and is made up of a molecular sequence found on a section of DNA. Each gene is found on a precise location on a chromosome.

Menorrhagia—Excessively heavy menstrual flow with cycles of normal length. It is also called hypermenorrhea.

Mutation—A permanent change in the genetic material that may alter a trait or characteristic of an individual, or manifest as disease, and can be transmitted to offspring.

Platelets—Small disc-shaped structures that circulate in the blood stream and participate in blood clotting.

Prenatal testing—Testing for a disease, such as a genetic condition, in an unborn baby.

Protein—Important building blocks of the body, composed of amino acids, involved in the formation of body structures and controlling the basic functions of the human body.

Skin hematoma—Blood from a broken blood vessel that has accumulated under the skin.

von Willebrand factor (VWF)—A protein found in the blood that is involved in the process of blood clotting.

Prenatal testing

If one parent has been diagnosed with an autosomal dominant form of VWD or both parents are carriers for an autosomal recessive form of VWD, then prenatal testing can be considered. If the parent with an autosomal dominant form of VWD possesses a detectable gene change or both parents who are carriers for an autosomal recessive form of VWD possess detectable mutations, then DNA testing of their fetus would be available. DNA testing can be performed through **amniocentesis** or **chorionic villus sampling**. If the DNA change in the parent(s) is unknown then prenatal testing can sometimes be performed through biochemical testing of blood obtained

WWW.BOOKBAZ.IR

from the fetal umbilical cord, which is less accurate and is associated with a higher risk of pregnancy loss.

Treatment

VWD is most commonly treated by replacement of VWF through the administration of blood products that contain VWF or through treatment with desmopressin (DDAVP, 1-deamino-8-D-arginine vasopressin). DDAVP functions by increasing the amount of factor VIII and VWF in the bloodstream. Treatment with blood products or DDAVP may be started in response to uncontrollable bleeding or may be administered prior to procedures such as surgeries or dental work. The type of treatment chosen depends on the type of VWD and a patient's response to a preliminary treatment trial.

Treatment with desmopressin

DDAVP is the most common treatment for people with type 1 VWD. About 80% of people with type 1 VWD respond to DDAVP therapy. Treatment with DDAVP can also be used to treat some people with type 2 VWD. Patients with Type 2B VWD should not be treated with this medication since DDAVP can induce dangerous platelet clumping. Type 3 VWD should not be treated with DDAVP since this medication does not increase the level of VWF in type 3 patients. DDAVP should only be used in people who have been shown to be responsive through a pre-treatment trial transfusion with this medication.

DDAVP can be administered intravenously or through a nasal inhaler. DDAVP has relatively few side effects although some people may experience facial flushing, tingling sensations, and headaches after treatment with this medication. Often treatment with this medication is only required prior to invasive surgeries or dental procedures.

Treatment with blood products

Patients who are unable to tolerate or are unresponsive to drug-based treatments are treated with concentrated factor VIII obtained from blood products. Not all factor VIII concentrates can be used since some do not contain enough VWF. The concentrate is treated to kill most viruses, although caution should be used since not all types of viruses are destroyed. If the factor VIII concentrates are unable to manage a severe bleeding episode, then blood products called cryoprecipitates, which contain concentrated amounts of VWF, or platelet concentrates should be considered. Caution should be used when treating with these blood products since they are not treated to kill viruses.

Other treatments and precautions

Medications called fibrinolytic inhibitors can be helpful in the control of intestinal, mouth, and nose bleeding. Estrogens such as those found in **oral contraceptives** increase the synthesis of VWF and can sometimes be used in the long-term treatment of women with mild to moderate VWD. Estrogens are also sometimes used prior to surgery in women with type 1 VWD. Some topical agents are available to treat nose and mouth bleeds.

Endometrial ablation, or the removal of the lining of the uterus by means of electrocautery or other thermal methods, is sometimes recommended as a treatment for menorrhagia associated with VWD. This procedure appears to be successful in lowering the amount of bleeding that these women experience during their menstrual periods.

Patients with VWD should avoid taking **aspirin**, ibuprofen, or other NSAIDs, which can increase their susceptibility to bleeding. They should also inform their dentist of their diagnosis, as many routine dental procedures can cause bleeding from the gums. People with severe forms of VWD should avoid activities that increase their risk of injury such as contact sports.

Patients with type 3 VWD living in the United States may wish to contact one of the 146 federally funded Hemophilia Treatment Centers (HTCs) for advice about prophylactic treatment and general follow-up.

Prognosis

The prognosis for VWD disease is generally fairly good, and most individuals have a normal lifespan. The prognosis can depend, however, on accurate diagnosis and appropriate medical treatment.

Vulvar cancer

Definition

Vulvar cancer refers to an abnormal, cancerous growth in the external female genitalia.

Description

Vulvar cancer is a rare disease that occurs mainly in elderly women. The vulva refers to the external female genitalia, which includes the labia, the opening of the vagina, the clitoris, and the space between the vagina and anus (perineum). There are two pairs of labia (a Latin term meaning lips). The labia meet to protect the openings of the vagina and the tube that connects to the bladder (urethra). The outer, most prominent folds of skin are called labia majora, and the smaller, inner skin folds are called labia minora. Vulvar cancer can affect any part of the female genitalia, but usually affects the labia.

Approximately 70% of vulvar cancers involve the labia (usually the labia majora), 15–20% involve the clitoris, and 15–20% involve the perineum. For approximately 5% of the cases, the cancer is present at more than one location. For approximately 10% of the cases, so much of the vulva is affected by cancer that the original location cannot be determined. Vulvar cancer can spread to nearby structures including the anus, vagina, and urethra.

Most vulvar cancers are squamous cell carcinomas. Squamous cells are the main cell type of the skin. Squamous cell carcinoma often begins at the edges of the labia majora or labia minora or the area around the vagina. This type of cancer is usually slow-growing and may begin with a precancerous condition referred to as vulvar intraepithelial neoplasia (VIN), or dysplasia. This means that precancerous cells are present in the surface layer of skin.

Other, less common types of vulvar cancer are **melanoma**, **basal cell carcinoma**, adenocarcinomas, Paget's disease of the vulva, and tumors of the connective tissue under the skin. Melanoma, a cancer that develops from the cells that produce the pigment that determines the skin's color, can occur anywhere on the skin, including the vulva. Melanoma is the second most common type of vulvar cancer, and accounts for 5–10% of the cases. Half of all vulvar melanomas involve the labia majora. Basal cell carcinoma, which is the most common type of cancer that occurs on parts of the skin exposed to the sun, very rarely occurs on the vulva. Adenocarcinomas develop from glands, including the glands at the opening of the vagina (Bartholin's glands) that produce a mucus-like lubricating fluid.

Vulvar cancer is most common in women over 50 years of age. The median age at diagnosis is 65–70 years old. Additional risk factors for vulvar cancer include having multiple sexual partners, **cervical cancer**, and the presence of chronic vaginal and vulvar inflammations. This type of cancer is often associated with sexually transmitted diseases.

Vulvar cancer is most common in women who are between the ages of 65 and 75 years. In the United States there are approximately 3,000 new cases of vulvar cancer diagnosed each year. Vulvar cancer accounts for only 1% of all cancers in women. Approximately 5% of all gynecologic cancers occur on the vulva. For unknown reasons, the incidence of vulvar cancer seems to be rising.

Causes and symptoms

Cancer is caused when the normal mechanisms that control cell growth become disturbed, causing

WWW.BOOKBAZ.IR

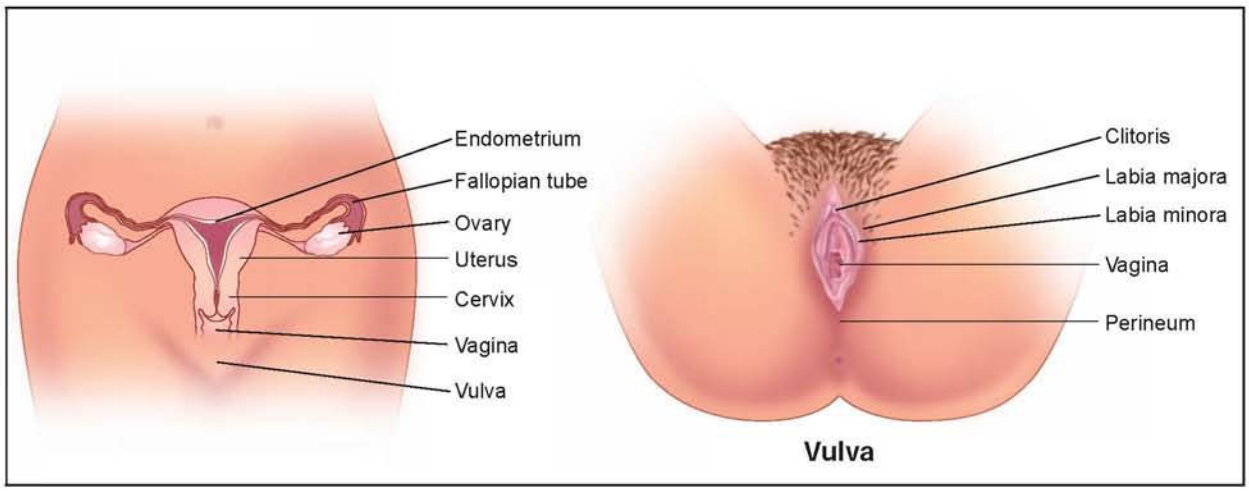

Illustration showing the female reproductive anatomy (left) and the anatomy of the vulva (right). *(Illustration by Electronic Illustrators Group. © Cengage Learning®.)*

the cells to continually grow without stopping. This is usually the result of damage to the DNA in the cell. Although the cause of vulvar cancer is unknown, studies have identified several risk factors for vulvar cancer. These include:

- Vulvar intraepithelial neoplasia (VIN). This abnormal growth of the surface cells of the vulva can sometimes progress to cancer.
- Infection with human papillomavirus (HPV). This virus is sexually transmitted and can cause genital warts. Although HPV DNA can be detected in most cases of vulvar intraepithelial neoplasia, it is detected in fewer than half of all cases of vulvar cancer. Therefore, the link between HPV infection and vulvar cancer is unclear. It is theorized that two classes of vulvar cancer exist: one that is associated with HPV infection and one that is not.
- Herpes simplex virus 2 (HSV2). This sexually transmitted virus is also associated with increased risk for vulvar cancer.
- Cigarette smoking. Smoking in combination with infection by HPV or HSV2 was found to be a particularly strong risk factor for vulvar cancer.
- Infection with human immunodeficiency virus (HIV). This virus, which causes AIDS, decreases the body's immune ability, leaving it vulnerable to a variety of diseases, including vulvar cancer.
- Chronic vulvar inflammation. Long term irritation and inflammation of the vulva and vagina, which may be caused by poor hygiene, can increase the risk of vulvar cancer.
- Abnormal Pap smears. Women who have had abnormal Pap smears are at an increased risk of developing vulvar cancer.
- Chronic immunosuppression. Women who have had long-term suppression of their immune system caused by disease (such as certain cancers) or medication (such as those taken after organ transplantation) have an increased risk of developing vulvar cancer.

The hallmark symptom of vulvar cancer is **itching** (pruritus), which is experienced by 90% of the women afflicted by this cancer. The cancerous lesion is readily visible. Unfortunately, because of embarrassment or denial, it is not uncommon for women to delay medical assessment of vulvar abnormalities. Any abnormalities should be reported to a gynecologist.

If squamous cell vulvar cancer is present, it may appear as a raised red, pink, or white bump (nodule). It is often accompanied by **pain**, bleeding, vaginal discharge, and painful urination. Malignant melanoma of the vulva usually appears as a pigmented, ulcerated growth. Other types of vulvar cancer may appear as a distinct mass of tissue, sore and scaly areas, or cauliflower-like growths that look like **warts**.

Diagnosis

A gynecological examination will be used to observe the suspected area. During this examination, the physician may use a special magnifying instrument called a colposcope to view the area better. Additionally, the area may be treated with a dilute solution of acetic acid, which causes some abnormal areas to turn white, making them easier to see. During this examination, if any area is suspected of being abnormal, a tissue sample (biopsy) will be taken. The biopsy can be performed in the doctor's office with the use of local anesthetic. A wedge-shaped piece of tissue, which

contains the suspect lesion with some surrounding normal skin and the underlying skin layers and connective tissue, will be removed. Small lesions will be removed in their entirety (excisional biopsy). The diagnosis of cancer depends on a microscopic analysis of this tissue by a pathologist.

The diagnosis for vulvar cancer will determine how advanced the cancer is and how much it has spread. This is determined by the size of the tumor and how deep it has invaded the surrounding tissue and organs, such as the lymph nodes. It will also be determined if the cancer has metastasized, or spread to other organs. Tests used to determine the extent of the cancer include x ray and computed tomography scan (CT scan). Endoscopic examination of the bladder (**cystoscopy**) and/or rectum (proctoscopy) may be performed if it is suspected that the cancer has spread to these organs.

Treatment

Clinical staging

The International Federation of Gynecology and Obstetrics (FIGO) has adopted a surgical staging system for vulvar cancer. The stage of cancer is determined after surgery. The previous clinical staging system for vulvar cancer is no longer used. Vulvar cancer is categorized into five stages (0, I, II, III, and IV) which may be further subdivided (A and B) based on the depth or spread of cancerous tissue. The FIGO stages for vulvar cancer are:

- Stage 0. Vulvar intraepithelial neoplasia.
- Stage I. Cancer is confined to the vulva and perineum. The lesion is less than 2 cm (about 0.8 in) in size.
- Stage II. Cancer is confined to the vulva and perineum. The lesion is larger than 2 cm (larger than 0.8 in) in size.
- Stage III. Cancer has spread to the vagina, urethra, anus, and/or the lymph nodes in the groin (inguinofemoral).
- Stage IV. Cancer has spread to the bladder, bowel, pelvic bone, pelvic lymph nodes, and/or other parts of the body.

Treatments

Treatment for vulvar cancer will depend on its stage and the patient's general state of health. Surgery is the mainstay of treatment for most cases of vulvar cancer.

SURGERY. The primary treatment for stage I and stage II vulvar cancer is surgery to remove the cancerous lesion and possibly the inguinofemoral lymph nodes. Removal of the lesion may be done by laser, to burn off a minimal amount of tissue, or by scalpel (local excision), to remove more of the tissue. The choice will depend on the severity of the cancer. If a large area of the vulva is removed, it is called a vulvectomy. Radical vulvectomy removes the entire vulva. A vulvectomy may require skin grafts from other areas of the body to cover the wound and make an artificial vulva. Because of the significant morbidity and the psychosexual consequences of radical vulvectomy, there is a trend toward minimizing the extent of cancer excision. The specific inguinofemoral lymph node that would receive lymph fluid from the cancerous lesion, known as the sentinel node, may be exposed for examination (lymph node dissection) or removed (lymphadenectomy), especially in cases in which the cancerous lesion has invaded to a depth of more than 1 mm. Surgery may also be followed by **chemotherapy** and/or **radiation therapy** to kill additional cancer cells.

Surgical treatment of stage III and stage IV vulvar cancer is much more complex. Extensive surgery would be necessary to completely remove the cancerous tissue. Surgery would involve excision of pelvic organs (pelvic exenteration), radical vulvectomy, and lymphadenectomy. Because this extensive surgery comes with a substantial risk of complications, it may be possible to treat advanced vulvar cancer with minimal surgery by using radiation therapy and/or chemotherapy as additional treatment (adjuvant therapy).

An intraoperative technique that is used to identify the sentinel node in **breast cancer** and melanoma is being applied to vulvar cancer. This technique, called lymphoscintigraphy, is performed during surgical treatment of vulvar cancer and allows the surgeon to immediately identify the sentinel node. A radioactive compound (technetium 99m sulfur colloid) is injected into the cancerous lesion approximately two hours prior to surgery. This injection causes little discomfort, so local **anesthesia** is not required. During surgery, a radioactivity detector is used to locate the sentinel node and any other nodes to which cancer has spread. Although in the experimental stage, vulvar lymphoscintigraphy shows promise in reducing morbidity and hospital length of stay.

The most common complication of vulvectomy is the development of a tumor-like collection of clear liquid (wound seroma). Other surgical complications include **urinary tract infection**, wound infection, temporary nerve injury, fluid accumulation (**edema**) in the legs, **urinary incontinence**, falling or sinking of the genitals (genital prolapse), and **blood clots** (thrombus).

WWW.BOOKBAZ.IR

RADIATION THERAPY. Radiation therapy uses high-energy radiation from x rays and gamma rays to kill the cancer cells. The skin in the treated area may become red and dry and may take as long as a year to return to normal. **Fatigue**, upset stomach, **diarrhea**, and nausea are also common complaints of women having radiation therapy. Radiation therapy in the pelvic area may cause the vagina to become narrow as scar tissue forms. This phenomenon, known as vaginal stenosis, makes intercourse painful.

CHEMOTHERAPY. Chemotherapy uses **anticancer drugs** to kill the cancer cells. The drugs are given by mouth (orally) or intravenously. They enter the bloodstream and can travel to all parts of the body to kill cancer cells. Generally, a combination of drugs is given because it is more effective than a single drug in treating cancer. The side effects of chemotherapy are significant and include stomach upset, **vomiting**, appetite loss, hair loss, mouth or vaginal sores, fatigue, menstrual cycle changes, and **premature menopause**. There is also an increased chance of infections.

Alternatives

Although alternative and complementary therapies are used by many cancer patients, very few controlled studies on the effectiveness of such therapies exist. Mind-body techniques such as prayer, **biofeedback**, visualization, **meditation**, and **yoga** have not shown any effect in reducing cancer but can reduce **stress** and lessen some of the side effects of cancer treatments. Clinical studies of hydrazine sulfate found that it had no effect on cancer and even worsened the health and well-being of the study subjects. One clinical study of the drug amygdalin (Laetrile) found that it had no effect on cancer. Laetrile can be toxic and has caused death. Shark cartilage, although highly touted as an effective cancer treatment, is an improbable therapy that has not been the subject of clinical study.

The American Cancer Society has found that the "metabolic diets" pose serious risk to the patient. The effectiveness of the macrobiotic, Gerson, and Kelley **diets** and the Manner metabolic therapy has not been scientifically proven. The FDA was unable to substantiate the anticancer claims made about the popular Cancell treatment.

There is no evidence for the effectiveness of most over-the-counter herbal cancer remedies. However, some herbals have shown an anticancer effect. As shown in clinical studies, Polysaccharide krestin, from the mushroom *Coriolus versicolor*, has significant effectiveness against cancer. In a small study, the green alga *Chlorella pyrenoidosa* has been shown to have anticancer activity. In a few small studies, evening primrose oil has shown some benefit in the treatment of cancer.

KEY TERMS

Adjuvant therapy—A treatment that is intended to aid primary treatment. Adjuvant treatments for vulvar cancer are radiation therapy and chemotherapy.

Biopsy—Removal of a small piece of tissue for microscopic examination. This is done under local anesthesia and removed by either using a scalpel or a punch, which removes a small cylindrical portion of tissue.

Colposcope—An instrument used for examination of the vagina and cervix. Part of the instrument includes a magnifying lens for better visualization.

Metastasis—The movement of cancer cells from one area of the body to another. This occurs through the blood vessels or the lymph vessels.

Pelvic exenteration—Surgical removal of the organs of the true pelvis which includes the uterus, vagina, and cervix.

Sentinel lymph node—The first lymph node to receive lymph fluid from a tumor. If the sentinel node is cancer-free, then it is likely that the cancerous cells have not metastasized.

Prognosis

Factors that are correlated with disease outcome include the diameter and depth of the cancerous lesion, involvement of local lymph nodes, cell type, HPV status, and age of the patient. Vulvar cancers that are HPV positive have a better prognosis than those that are HPV negative. The five-year survival rate is 98% for stage I vulvar cancer and 87% for stage II vulvar cancer. The survival rate drops steadily as the number of affected lymph nodes increases. The survival rate is 75% for patients with one or two, 36% for those with three or four, and 24% for those with five or six involved lymph nodes. The previous statistics were obtained from studies of patients who received surgical treatment only and cannot be used to determine survival rates when adjuvant therapy is employed.

Vulvar cancer can spread locally to encompass the anus, vagina, and urethra. Because of the anatomy of the vulva, it is not uncommon for the cancer to spread

to the local lymph nodes. Advanced stages of vulvar cancer can affect the pelvic bone. The lungs are the most common site for vulvar cancer metastasis. Metastasis through the blood (hematogenous spread) is uncommon.

Prevention

The risk of vulvar cancer can be decreased by avoiding risk factors, most of which involve lifestyle choices. Specifically, to reduce the risk of vulvar cancer, women should not smoke and should refrain from engaging in unsafe sexual behavior. Good hygiene of the genital area to prevent infection and inflammation may also reduce the risk of vulvar cancer.

Because vulvar cancer is highly curable in its early stages, women should consult a physician as soon as a vulvar abnormality is detected. Regular gynecological examinations are necessary to detect precancerous conditions that can be treated before the cancer becomes invasive. Because some vulvar cancer is a type of **skin cancer**, the American Cancer Society also recommends self-examination of the vulva using a mirror. If **moles** are present in the genital area, women should employ the ABCD rule:

- Asymmetry. A cancerous mole may have two halves of unequal size.
- Border irregularity. A cancerous mole may have ragged or notched edges.
- Color. A cancerous mole may have variations in color.
- Diameter. A cancerous mole may have a diameter wider than 6 mm (1/4 in).

Vulvodynia

Definition

Vulvodynia is chronic **pain** of the vulva—the external or visible portion of the female genitalia—in the absence of vulvar or vaginal infection or skin disease. Vulvodynia is not a well-defined condition and its cause is usually unknown.

Demographics

Vulvodynia can affect any female of any age, although the onset of symptoms appears to be highest among women aged 18–25 and lowest in women over age 35. It has been estimated that at least 18% of women suffer from vulvodynia at some point in their lives. Approximately one-half of these women seek treatment. It has been estimated that about 15% of women visiting private gynecologists and about 1% of those visiting genitourinary medical clinics suffer from localized vulvodynia. Generalized vulvodynia appears to be more common in postmenopausal women and in younger women who have had back injuries.

Description

In 2003 the International Society for the Study of Vulvovaginal Disease (ISSVD) adopted a new classification system for vulvodynia: generalized vulvodynia is pain that extends beyond the vulva to other parts of the genitalia and pelvis; localized vulvodynia is pain that is restricted to the vestibule of the vulva—the region immediately surrounding the opening of the

WWW.BOOKBAZ.IR

vagina and urethra. Both types of vulvodynia are further classified as:

- provoked—sexual, nonsexual, or both—depending whether the pain occurs with sex and/or with other activities
- unprovoked—pain that is constant or occurs unpredictably and is not related to specific activities
- mixed—both provoked and unprovoked

Provoked vulvodynia is pain that occurs during or after pressure is applied to the vulva. Examples of activities or factors that can provoke vulvodynia include:

- touching the vestibule
- intercourse or other sexual activity
- tampon insertion
- a gynecological exam
- urination
- sitting for a long period
- bicycle or horseback riding
- jogging or other exercise
- tight-fitting underwear or pants

Older terms for vulvodynia continue to be used. Older terms for generalized vulvodynia include dysesthetic vulvodynia and generalized vulvar dysesthesia. Older terms for localized vulvodynia include vulvar or vulval vestibulitis syndrome (VVS) and provoked vestibulodynia. Another older classification system distinguishes between organic vulvodynia, in which a cause can be identified, and essential vulvodynia, in which a cause cannot be identified. A distinction may also be made between sexually provoked primary and secondary vulvodynia, depending on whether pain occurred with a woman's first vaginal penetration or developed after a period of pain-free vaginal penetration, respectively.

As with other types of chronic pain, vulvodynia can have a significant impact on the quality of life. It may interfere with daily activities including sitting, walking, physical **exercise**, and social interactions. Sexual intercourse may be painful or impossible. Vulvodynia can lead to exhaustion and depression. In extreme cases a woman may become bedridden.

Risk factors

One study indicated that women who experienced pain when first using a tampon were seven to eight times more likely to have vulvodynia at some point in their lives. Between 10% and 25% of women with interstitial cystitis—a bladder condition that causes frequent urination with burning—also have symptoms of vulvodynia. Other possible risk factors include:

- infection of or trauma to the genitalia
- laser treatments or surgery on the external genitalia
- diabetes
- precancerous or cancerous conditions of the cervix
- a history of sexual abuse

Causes and symptoms

Although the causes of vulvodynia are unknown, there are many suggested causes, including:

- abnormalities of embryonic development
- hypersensitivity to infection
- recurrent infections
- inflammation
- rashes
- allergies or chemical irritation
- overuse of topical medications
- irritation from high oxalate levels in the urine
- genetic or inherited susceptibility to pain, chronic vestibular inflammation, or infection
- immune system factors or autoimmune responses
- injury to or irritation of vulvar or pelvic nerves or an increased nerve fiber density
- hormonal changes, including those that occur with menstrual cycles, menopause, or use of birth control pills
- pelvic floor muscle weakness or spasm

Contact or allergic **dermatitis** or chemical irritation resulting in vulvodynia can be caused by:

- soap
- shampoo
- perfume
- laundry detergent
- fabric softener
- scented or dyed toilet paper
- scented menstrual pads or tampons
- feminine hygiene products such as vulvar wipes, deodorants, or douches
- sexual lubricants
- spermicides
- some medications, particularly topical steroids
- synthetic underwear
- excessive vaginal discharge
- urine or feces

Symptoms of vulvodynia vary greatly in both type and severity. The condition usually begins suddenly and

KEY TERMS

Autoimmune response—A response in which the immune system's antibodies or T cells attack the body's own proteins, cells, or tissues.

Colposcopy—The use of a special microscope—a colposcope—to view the genitalia.

Contact dermatitis—Irritant dermatitis; direct skin contact with a substance that causes inflammation in some people.

Hymen—A membrane that partially or completely covers the vaginal opening.

Interstitial cystitis—Chronic inflammation of the bladder; sometimes associated with vulvodynia.

Labia majora—Major lips; mounds of tissue forming the lateral boundaries of the vulva.

Labia minora—Minor lips; narrow folds of tissue between the labia major, on either side of the urethral and vaginal openings.

Mons pubis—The fatty tissue over the area where the pubic bones meet.

Oxalate—A salt of oxalic acid produced during metabolism and excreted in the urine.

Perineum—The area between the external genitalia and the anus.

Vestibule—Vestibule of the vulva or vagina; the space between the labia minora containing the openings of the vagina and urethra.

Vestibulectomy—Surgical removal of the vestibule and hymen.

Vulva—The external female genitalia including the mons pubis, labia majora and minora, clitoris, vestibule, glands, and the vaginal opening.

may last for months or years. The most common symptom is a painful burning sensation in the genitalia. Sometimes painful sexual intercourse is the first symptom. The pain may be intermittent or constant and localized or generalized throughout the pelvic region. Other common sensations of vulvodynia include:

- irritation
- tenderness
- stinging
- rawness or dryness
- intense itching
- soreness
- aching
- stretching of the skin in the vestibule
- throbbing
- swelling
- sharp, knife-like pain

Generalized vulvodynia is characterized by pain throughout the genitalia—not just in the vestibule—or in different areas at different times. Areas commonly affected include the:

- vestibule
- hymen
- introitus—the membranes surrounding the vaginal opening
- small or minor vestibular glands around the vaginal opening
- vulvovaginal (Batholin's) glands located on each side of the vaginal opening
- paraurethral (Skene's) glands located on each side of the urethral opening
- labia minora or inner labia
- labia majora or outer labia

Some women also experience pain in the clitoris, the perineum, the mons pubis, the anus, the inner thighs, and the lower back.

Diagnosis

Examination

A diagnosis of vulvodynia is made on the basis of pain or burning that lasts for more than three months with no apparent infection or **skin lesions**. Sometimes the vulvar tissue is inflamed, but often it appears completely normal. Other conditions that can cause chronic vulvar pain may coexist with vulvodynia, and many women are misdiagnosed for years or told that they have a chronic yeast infection or a psychological disorder. It is not uncommon for women to visit at least five doctors before vulvodynia is diagnosed.

Diagnosis includes:

- a medical history
- questions about symptoms, sexual activity, diet, feminine hygiene, and medications
- an examination of the vulva and vagina for signs of infection or a skin disorder
- a pelvic examination
- use of a magnifying glass to look for abnormalities

Tests

- a "touch test" with a cotton-tipped applicator to reveal painful areas or points

WWW.BOOKBAZ.IR

- culturing of vaginal secretions to test for yeast and bacteria
- blood tests for levels of the sex hormones estrogen, progesterone, and testosterone

Procedures

A colposcopy—an examination with a special magnifying lens—may be performed to look for inflamed surface blood vessels. A tissue biopsy—the removal of a small piece of tissue for microscopic examination—may be performed, particularly if skin lesions are present.

Treatment

Traditional

There is no cure for vulvodynia. Because vulvodynia has multiple causes and symptoms vary greatly, no single treatment is appropriate for all women. Although usually treated with medications, techniques such as neurostimulation are also used. Vestibulectomy—surgical removal of the vestibule and hymen—is sometimes used as a last resort. Laser treatments to destroy the irritated tissue have not proved successful and may worsen the condition.

Drugs

Symptoms of vulvodynia may be treated with:

- creams or oral medications for yeast infections
- topical anesthetics, such as viscous or liquid five percent lidocaine ointment (Xylocaine) for temporary relief
- cortisone creams
- corticosteroid ointments, such as triamcinolone or desoximetasone
- hormone creams, such as topical estrogen or testosterone
- antihistamines, such as Atarax or Vistaril
- oral pain-blocking medications, such as tricyclic antidepressants, serotonin-norepinephrine reuptake inhibitors, or anticonvulsants
- topical compounded formulations of antidepressants or anticonvulsants
- opioid painkillers
- interferon—an antiviral drug—injected into the vulva, particularly in women who also have human papillomavirus
- a nerve block—the injection or spinal pump infusion of an anesthetic, sometimes combined with an anti-inflammatory
- trigger-point injections of a steroid or bupivacaine

Alternatives

Alternative treatments for vulvodynia include:

- pelvic floor therapy—physical and exercise therapy to strengthen and relax the pelvic-floor muscles
- biofeedback with sensitive detectors designed for use on the vulva
- acupuncture
- cognitive behavioral therapy
- hypnotherapy

Home remedies

Gentle vulvar hygiene is extremely important for treating vulvodynia:

- cleaning the vulva with water only
- bathing with mild soap
- eliminating any potentially irritating products, such as douches, vaginal wipes, deodorants, bubble bath, or deodorant-containing pads or tampons
- douching with baking soda to relieve inflammation
- wearing all-cotton underwear
- avoiding tight-fitting underwear, pantyhose, and underwear at night
- applying cool gel packs to the vulvar area to reduce pain and itching
- taking cool or lukewarm sitz baths to relieve irritation and burning
- applying a compress of Aveeno—a powdered oatmeal bath treatment—to the vulva three to four times per day
- using lubrication for sexual intercourse
- aerobic exercising that does not put pressure directly on the vulva

Vulvodynia that might be caused by acidic, irritating oxalate crystals in the urine may be helped by following a low-carbohydrate, low-oxalate diet for three months to a year:

- eliminating all foods with more than 10 mg of oxalate per serving
- limiting moderate (2–10 mg per serving) oxalate-containing foods to three servings per week
- drinking 12–14 cups of water per day
- taking calcium citrate supplements without vitamin D approximately 45 minutes before eating to decrease oxalate in the urine

Prognosis

Vulvodynia sometimes disappears spontaneously and often improves over time without treatment.

Although treatment—especially **corticosteroids** or the tricyclic antidepressant amitriptyline—often results in partial or complete relief of symptoms, this may take weeks, months, or even years, and some women are never completely symptom free. Vestibulectomy has the highest success rate of any treatment.

Prevention

There are numerous measures for potentially preventing or relieving symptoms of vulvodynia. These include:

- using soft, white or unbleached, unscented toilet tissue
- using 100%-cotton unscented menstrual pads and tampons
- avoiding soap and shampoo in the vulvar region
- avoiding bubble bath, feminine hygiene products, perfumed creams and soaps, petroleum jelly, and bath oils
- washing the vulva frequently with cool or lukewarm water
- drying the perineum with a hair dryer on the cool setting
- urinating before the bladder is full
- rinsing the vulva with water from a squeeze bottle after urination
- using a bidet
- eating fiber from whole grains, fruits, vegetables, and psyllium products to prevent constipation
- drinking eight glasses of water daily
- sitting on a foam rubber donut and standing periodically when sitting for long periods
- using relaxation techniques

Clothing and laundry suggestions include:

- wearing all-white cotton underwear, washing new underwear before use, and not wearing underwear at night
- wearing loose-fitting skirts and pants
- avoiding pantyhose and jeans
- wearing wicking underwear for exercise
- promptly removing wet bathing suits and exercise clothing
- washing clothes in a dermatologically approved detergent or baking soda soap
- double rinsing underwear and other clothing that contacts the vulva
- avoiding fabric softener and dryer sheets

Advice on physical activity includes:

- avoiding activities that put direct pressure on the vulva, such as bicycle and horseback riding
- limiting intense exercise that applies friction to the vulva
- applying a frozen gel pack wrapped in a towel after exercising to relieve symptoms
- performing stretching and relaxation exercises such as yoga
- avoiding hot tubs and highly-chlorinated swimming pools

Suggestions for sexual activities include:

- applying a topical anesthetic, such as 5% lidocaine gel, to the vestibule 10–15 minutes before intercourse
- applying pure almond oil, vegetable oil, or a water–soluble, glycerin-containing lubricant
- avoiding lubricants containing preservatives or other chemicals
- avoiding contraceptive creams, spermicides, and devices that may irritate the vulva
- applying ice or a frozen blue gel pack after intercourse to prevent burning
- urinating and rinsing the vulva with cool water after intercourse

Waldenströ disease *see* **Waldenström's macroglobulinemia**

Waldenström's macroglobulinemia

Definition

Waldenstrom's macroglobulinemia is a rare, chronic cancer of the immune system that is characterized by hyperviscosity, or thickening, of the blood.

Description

Waldenstrom's (Waldenstrom, Waldenstroem's) macroglobulinemia (WM) is a lymphoma, or cancer of the lymphatic system. It was first identified in 1944, by the Swedish physician Jan Gosta Waldenstrom, in patients who had a thickening of the serum, or liquid part, of the blood. Their blood serum contained a great deal of a very large molecule called a globulin. Thus, the disorder is called macroglobulinemia.

Lymphomas are cancers that originate in tissues of the lymphatic system. All lymphomas other than Hodgkin's disease, including WM, are known collectively as non-Hodgkin's lymphomas. There are 13 major types of non-Hodgkin's lymphomas and others that are very rare. Other names that are sometimes used for WM include lymphoplasmacytic lymphoma, lymphoplasmacytic leukemia, macroglobulinemia of Waldenstrom, primary macroglobulinemia, Waldenstrom's syndrome, Waldenstrom's purpura, and hyperglobulinemic purpura. Purpura refers to purple spots on the skin, resulting from the frequent bleeding and bruising that can be a symptom of WM.

WM is classified as a low-grade or indolent form of lymphoma because it is a slow-growing cancer that produces fewer symptoms than other types of lymphomas. WM most often affects males over the age of 65. Frequently, this disease produces no symptoms and does not require treatment. It has not been studied as extensively as other types of lymphoma.

The lymphatic system

The lymphatic system is part of the body's immune system for fighting disease and part of the blood-producing system. It includes the lymph vessels and nodes, spleen, bone marrow, and thymus. The narrow lymphatic vessels carry lymphatic fluid from throughout the body. The lymph nodes are small, pea-shaped organs that filter the lymphatic fluid and trap foreign substances, including viruses, bacteria, and cancer cells. The spleen, in the upper left abdomen, removes old cells and debris from the blood. The bone marrow, the spongy tissue inside the bones, produces new blood cells.

B lymphocytes or B cells are white blood cells that recognize disease-causing organisms. They circulate throughout the body in the blood and lymphatic fluid. Each B lymphocyte recognizes a specific foreign substance, or antigen. When it encounters its specific antigen, the B cell begins to divide and multiply, producing large numbers of identical (monoclonal), mature plasma cells. These plasma cells produce large amounts of antibody that are specific for the antigen. Antibodies are large proteins called immunoglobulins (Igs) that bind to and remove the specific antigen.

A type of Ig, called IgM, is part of the early immune response. The IgM molecules form clusters in the bloodstream. When these IgM clusters encounter their specific antigen, usually a bacterium, they cover it so that it can be destroyed by other immune system cells.

Plasma cell neoplasm

WM is a type of plasma cell neoplasm or B-cell lymphoma. These are lymphomas in which certain

WWW.BOOKBAZ.IR

plasma cells become abnormal, or cancerous, and begin to grow uncontrollably. In WM, the cancerous plasma cells overproduce large amounts of identical (monoclonal) IgM antibody. This IgM also is called M protein, for monoclonal or myeloma protein.

Macroglobulinemia refers to the accumulation of the M protein in the serum of the blood. This large amount of M protein can cause the blood to thicken, causing hyperviscosity. The malignant plasma cells of some WM patients also produce and secrete partial immunoglobulins called light chains, or Bence-Jones proteins. The malignant plasma cells can invade various tissues, including the bone marrow, lymph nodes, and spleen, causing these tissues to swell.

WM accounts for about 1–2% of non-Hodgkin's lymphomas. It is estimated that it may affect about five out of every 100,000 people. It usually affects people over the age of 50 and most often develops after age 65. It is more common in men than in women. In the United States, WM is more common among Caucasians than among African Americans. The disease can run in families.

Causes and symptoms

The cause of WM is not known.

Many individuals with WM have no symptoms of the disease. This is known as asymptomatic macroglobulinemia. When symptoms of WM are present, they may vary greatly from one individual to the next.

Hyperviscosity syndrome

At least 50% of individuals with WM have hyperviscosity syndrome, an increased viscosity or thickening of the blood caused by the accumulation of IgM in the serum. Hyperviscosity can cause a slowing in the circulation through small blood vessels. This condition can lead to a variety of symptoms:

- fatigue
- weakness
- rash
- bruising
- nose bleeds
- gastrointestinal bleeding
- weight loss
- night sweats
- increased and recurrent infections
- poor blood circulation in the extremities

Poor blood circulation, or Raynaud's phenomenon, can affect any part of the body, but particularly the fingers, toes, nose, and ears.

Cold weather can cause additional circulatory problems by further thickening the blood and slowing down circulation. In some cases, the excess blood protein may precipitate out of the blood in the cold, creating particles that can block small blood vessels. This is called cryoglobulinemia. The extremities may turn white, or a patchy red and white. The hands, feet, fingers, toes, ears, and nose may feel cold, numb, or painful.

Hyperviscosity may affect the brain and nervous system, leading to additional symptoms. These symptoms include:

- peripheral neuropathy, caused by changes in the nerves, leading to pain or numbness in the extremities
- dizziness
- headaches
- vision problems or loss of vision
- Mental confusion
- poor coordination
- temporary paralysis
- mental changes

Hyperviscosity can clog the tubules that form the filtering system of the kidneys, leading to kidney damage or kidney failure. Existing heart conditions can be aggravated by WM. In extreme cases, WM may result in **heart failure**. Late-stage WM also may lead to mental changes that can progress to **coma**.

Anemia

The accumulation of IgM in the blood causes an increase in the volume of the blood plasma. This effectively dilutes out the red blood cells and other blood components. The lowered concentration of red blood cells can lead to anemia and cause serious **fatigue**. Likewise, a deficiency in platelets (**thrombocytopenia**), which cause the blood to clot, can result in easy bleeding and bruising. As the cancer progresses, there may be abnormal bleeding from the gums, nose, mouth, and intestinal tract. There may be bluish discoloration of the skin. In the later stages of the disease, leukopenia, a deficiency in white blood cells, also can develop.

Organ involvement

In 5–10% of WM cases, the IgM may be deposited in tissues. Thus, some individuals with WM have enlargement of the lymph nodes, the spleen, and/or the liver.

If Bence-Jones proteins are produced by the malignant plasma cells, they may be deposited in the kidneys. There they can plug up the tiny tubules that

form the filtering system of the kidneys. This can lead to kidney damage and kidney failure.

Diagnosis

Since many individuals with WM have no symptoms, the initial diagnosis may result from blood tests that are performed for some other purpose. Blood cell counts may reveal low red blood cell and platelet levels. A **physical examination** may indicate enlargement of the lymph nodes, spleen, and/or liver. A retinal **eye examination** with an ophthalmoscope may show retinal veins that are enlarged or bleeding.

Blood and urine tests

Serum **protein electrophoresis** is used to measure proteins in the blood. In this laboratory procedure, serum proteins are separated in an electrical field, based on the size and electrical charge of the proteins. Serum **immunoelectrophoresis** uses a second antibody that reacts with IgM. A spike in the Ig fraction indicates a large amount of identical or monoclonal IgM in individuals with WM.

Normal serum contains 0.7-1.6 gm per deciliter (g/dL) of Ig, with no monoclonal Ig present. At serum IgM concentrations of 3-5 g/dL, symptoms of hyperviscosity often are present. However some individuals remain asymptomatic with IgM levels as high as 9 g/dL.

Urinalysis may indicate protein in the urine. A urine Bence-Jones protein test may indicate the presence of these small, partial Igs.

Bone marrow

Abnormal blood tests usually are followed by a bone marrow biopsy. In this procedure, a needle is inserted into a bone and a small amount of marrow is removed. Microscopic examination of the marrow may reveal elevated levels of lymphocytes and plasma cells. However, less than 5% of patients with WM have lytic bone lesions, caused by cancerous plasma cells in the bone marrow that are destroying healthy cells. Bone lesions can be detected with x rays.

Treatment

Clinical staging, to define how far a cancer has spread through the body, is the common method for choosing a cancer treatment. However, there is no generally accepted staging system for WM.

There also is no generally accepted course of treatment for WM. Treatment may not be necessary for asymptomatic macroglobulinemia. However, if IgM serum levels are very high, treatment may be initiated even in the absence of symptoms. If symptoms are present, treatment is directed at relieving symptoms and retarding the disease's development. Of major concern is the prevention or alleviation of blood hyperviscosity. Therefore, the initial treatment depends on the viscosity of the blood at diagnosis.

Hyperviscosity

Plasmapheresis, or plasma exchange **transfusion**, is a procedure for thinning the blood. In this treatment, blood is removed and passed through a cell separator that removes the plasma, containing the IgM, from the red and white blood cells and platelets. The blood cells are transfused back into the patient, along with a plasma substitute or donated plasma. Plasmapheresis relieves many of the acute symptoms of WM. Individuals with WM may be given fluid to counter the effects of hyperviscous blood.

Low blood cell counts

Treatments for low blood cell levels include:

- the drug Procrit to treat anemia
- transfusions with packed red blood cells to treat anemia in later stages of the disease
- antibiotics to treat infections caused by a deficiency in white blood cells
- transfusions with blood platelets

Chemotherapy

Chemotherapy, the use of anti-cancer drugs, helps to slow the abnormal development of plasma cells, but does not cure WM. It can reduce the amount of IgM in the bone marrow. In particular, chemotherapy is used to treat severe hyperviscosity and anemia that are caused by WM.

Chlorambucil (Leukeran), possibly in combination with prednisone, is the typical chemotherapy choice for WM. This treatment is effective in 57% of cases. These drugs are taken by mouth. Prednisone is a corticosteroid that affects many body systems. It has anti-cancer and anti-inflammatory effects and is an immune system suppressant. Other drug combinations that are used to treat WM include cyclophosphamide (Cytoxan), vincristine, and prednisone, with or without doxorubicin. Fludaribine, 2-chlorodeoxyadenosine, and **corticosteroids** also may be used.

side effects of chemotherapy may include:

- mouth sores
- nausea and indigestion
- hair loss

WWW.BOOKBAZ.IR

KEY TERMS

Anemia—Any condition in which the red blood cell count is below normal.

Antibody—Immunoglobulin produced by immune system cells that recognizes and binds to a specific foreign substance (antigen).

Antigen—Foreign substance that is recognized by a specific antibody.

Autosomal dominant—Genetic trait that is expressed when present on only one of a pair of non-sex-linked chromosomes.

B cell (B lymphocyte)—Type of white blood cell that produces antibodies.

Bence-Jones protein—Light chain of an immunoglobulin that may be overproduced in Waldenstrom's macroglobulinemia; it is excreted in the urine.

Biopsy—Removal of a small sample of tissue for examination under a microscope; used in the diagnosis of cancer.

Cryoglobulinemia—Condition in which protein in the blood forms particles in the cold, blocking blood vessels and leading to pain and numbness of the extremities.

Hyperviscosity—Unusually thick blood, caused by the accumulation of large proteins, such as immunoglobulins, in the serum.

Immunoelectrophoresis—Use of an electrical field to separate proteins in a mixture (such as blood or urine), on the basis of the size and electrical charge of the proteins; followed by the detection of an antigen (such as IgM), using a specific antibody.

Immunoglobulin (Ig)—Antibody such as IgM; large protein produced by B cells that recognizes and binds to a specific antigen.

Interferon alpha—Potent immune-defense protein; used as an anti-cancer drug.

Lymphatic system—The vessels, lymph nodes, and organs, including the bone marrow, spleen, and thymus, that produce and carry white blood cells to fight disease.

Lymphoma—Cancer that originates in lymphatic tissue.

M protein—Monoclonal or myeloma protein; IgM that is overproduced in Waldenstrom's macroglobulinemia and accumulates in the blood and urine.

Monoclonal—Identical cells or proteins; cells (clones) derived from a single, genetically distinct cell, or proteins produced by these cells.

Plasma cell—Type of white blood cell that produces antibodies; derived from an antigen-specific B cell.

Plasmapheresis—Plasma exchange transfusion; the separation of serum from blood cells to treat hyperviscosity of the blood.

Platelet—Cell that is involved in blood clotting.

Stem cell—Undifferentiated cell that retains the ability to develop into any one of numerous cell types.

- increased appetite
- nervousness
- insomnia

These side effects disappear after the chemotherapy is discontinued.

The long-term management of WM usually is accomplished through a combination of plasmapheresis and chemotherapy.

Alternatives

Biological therapy or immunotherapy, with the potent, immune system protein interferon alpha, is used to relieve the symptoms of WM. Interferon alpha works by boosting the body's immune response. Interferon can cause flu-like symptoms, such as **fever**, chills, and fatigue. It also can cause digestive problems and may affect blood pressure.

The drug rituximab, an antibody that is active against antibody-producing cells, is effective in about 30% of individuals with WM. Rituximab is a monoclonal antibody produced in the laboratory. Monoclonal antibody treatment may cause a an allergic reaction in some people.

Prognosis

There is no cure for WM. In general, patients go into partial or complete remission following initial treatments. However the disease is not cured and follow-up treatment may be necessary.

The prognosis for this cancer depends on an individual's age, general health, and genetic (hereditary) makeup. Males, individuals over age 60, and those with severe anemia have the lowest survival rates. The Revised European American Lymphoma (REAL) classification

system gives WM a good prognosis following treatment, with an average 5-year survival rate of 50-70%. However, many people with WM live much longer, some without developing any symptoms of the disease. About 16-23% of individuals with WM die of unrelated causes.

Prevention

There is no known prevention for WM.

Warts

Definition

Warts are small, benign growths caused by a viral infection of the skin or mucous membrane. The virus infects the surface layer. The viruses that cause warts are members of the human papilloma virus (HPV) family. Warts are not cancerous but some strains of HPV, usually not associated with warts, have been linked with cancer formation. Warts are contagious from person to person and from one area of the body to another on the same person.

Demographics

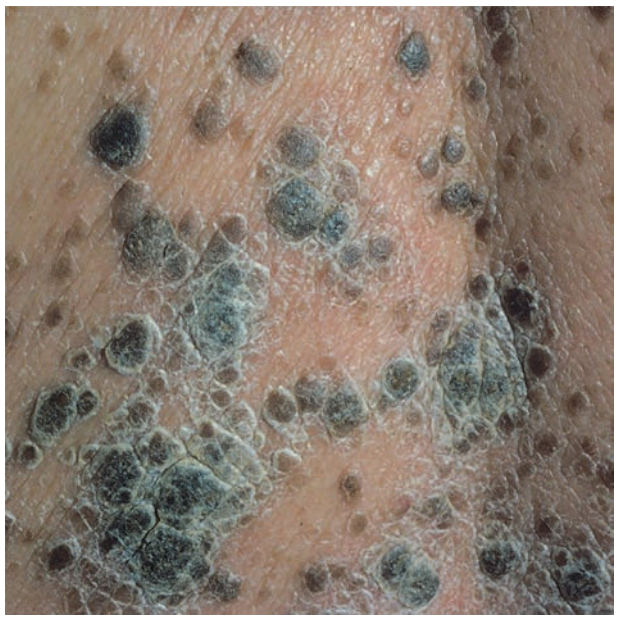
Warts are particularly common among children, young adults, and women. They affect about 7–10% of the U. S. population. The incidence of **genital warts** in the United States is around one million cases annually. It is estimated that approximately one in 272 have genital warts, which is roughly 0.37% of the population.

Description

There are close to 60 types of HPV that cause warts, each preferring a specific skin location. For instance, some types of HPV cause warts to grow on the skin, others cause them to grow inside the mouth, while still others cause them to grow on the genital and rectal areas. However, most can be active anywhere on the body. The virus enters through the skin and produces new warts after an incubation period of one to eight months. Warts are usually skin-colored and feel rough to the touch, but they also can be dark, flat, and smooth.

Warts on finger. *(CMSP/Getty Images.)*

WWW.BOOKBAZ.IR



Seborrhoeic warts appearing on a patient's back. *(Custom Medical Stock Photo, Inc.)*

Warts are passed from person to person, directly and indirectly. Some people are continually susceptible to warts, while others are more resistant to HPV and seldom get them. The virus takes hold more readily when the skin has been damaged in some way, which may explain why children who bite their nails tend to have warts located on their fingers. People who take a medication to suppress their immune system or are on long-term steroid use are also prone to a wart virus infection. This same is true for patients with **AIDS**.

Causes and symptoms

The more common types of warts include:

- common hand warts
- foot warts
- flat warts
- genital warts

Hand warts

Common hand warts grow around the nails, on the fingers, and on the backs of hands. They appear more frequently where skin is broken, such as in areas where fingernails are bitten or hangnails picked.

Foot warts

Foot warts are called plantar warts because the word *plantar* is the medical term for the sole of the foot, the area where the wart usually appears as a single lesion or as a cluster. Plantar warts, however, do not stick up above the surface like common warts. The ball of the foot, the heel and the plantar part of the toes are the most likely locations for the warts because the skin in those areas is subject to the most weight, pressure, and irritation, making a small break or crack more likely.

Plantar warts are familiar to all ages groups, appearing frequently in children between the ages of 12 and 16. Adolescents often come into contact with a wart virus in a locker room, swimming pool area, or by walking barefooted on dirty surfaces. The blood vessels feeding them are the black dots that are visible on the wart. If left untreated, these warts can grow to an inch or more in circumference and spread into clusters of several warts. They are known to be very painful at times, the **pain** usually compared to the feeling of a permanent stone in the shoe, particularly if the wart is on a pressure point of the foot. People with **diabetes mellitus** are prone to complications from plantar warts related to the development of sores or ulceration and the poor healing potential associated with diabetes.

Flat warts

Flat warts tend to grow in great numbers and are smaller and smoother than other warts. They can erupt anywhere, appearing more frequently on the legs of women, the faces of children, and on the areas of the face that are shaved by young adult males.

Genital warts

Genital warts, also called condyloma acuminata or venereal warts, are one of the most common causes of sexually transmitted disease (STD) in the United States. According to the *Journal of the American Medical Association's* STD Information Center, they are contracted by sexual contact with an infected person who carries HPV and are more contagious than other warts. It is estimated that two-thirds of the people who have sexual contact with a partner with genital warts will develop the disease within three months of contact. As a result, about one million new cases of genital warts are diagnosed in the United States each year.

Genital warts tend to be small flat bumps or they may be thin and tall. They are usually soft and not scaly like other warts. In women, genital warts appear on the genitalia, within the vagina, on the cervix, and around the anus or within the rectum. In men, genital warts usually appear on the tip of the penis but may also be found on the scrotum or around the anus. Genital warts can also develop in the mouth of a person who has had oral sexual contact with an infected person.

KEY TERMS

Condyloma acuminata—Another term for genital warts.

Cryotherapy—Freezing with liquid nitrogen for removal.

Endometritis—Inflammation of the endometrium or mucous membrane of the uterus.

Epidermis—The outer layer of human skin.

Human papilloma virus (HPV)—A family of viruses that causes hand warts, foot warts, flat warts, and genital warts.

Retinoic acid—Vitamin A_1 acid, which is used topically to treat acne.

Salicylic acid—An agent prescribed in the treatment of hyperkeratotic skin conditions and fungal infections.

Diagnosis

Patients who notice warts in their genital area should see a doctor. The doctor may be able to diagnose the warts with a simple examination. If the warts are small, the doctor may put a vinegar-like liquid on the skin, which makes the warts turn white and easier to see, and then use a magnifying glass to look for them.

Treatment

Home/self treatment

Many of the nonprescription wart remedies available at drug stores will remove simple warts from hands and fingers. These medications may be lotions, ointments, or plasters and work by chemically removing the skin that was affected by the wart virus. The chemicals are strong, however, and should be used with care since they can remove healthy as well as infected skin. These solutions should be avoided by diabetics and those with cardiovascular or other circulatory disorders whose skin may be insensitive and not appreciate irritation.

Flat warts are best treated with topical retinoides (retinoic acid) or a gel containing salicylic acid. The acid does not actually kill the wart virus, but waterlogs the skin so that the surface layer, with the virus, peels off. These products can take up to three months of treatment depending on the size and depth of the wart. Patches are also good to use. Rather than applying drops, a small pad is placed on the wart and left for 48 hours and then replaced with a new one. The patch usually contains a higher concentration of salicylic acid and may irritate the surrounding skin. If this occurs, patients should switch to a gel or stop medication for a period. To help the healing process for flat facial warts, men should shave with an electric shaver or temporarily grow a beard. Women with flat warts on areas that are shaved should use other methods to remove hair, such as depilatory cream or wax.

Professional treatment

Physicians should be consulted if there are no signs of progress after a month of self treatment. Doctors have many ways of removing warts, including using stronger topically applied chemicals than those available in drugstores. Some of these solutions include podofilox, topical podophyllum, and trichloracetic acid (TCA). Some burning and discomfort for one or more days following treatment can be expected. Although these chemicals are effective, they may not destroy all warts completely. A second method of removal is freezing or cryosurgery on the wart using liquid nitrogen. **Cryotherapy** is relatively inexpensive, does not require **anesthesia**, and usually does not result in scarring. Although temporarily uncomfortable, it provides an effective and safe way to deliver freezing temperatures to a particular area on the skin, and healing is usually quick. Physicians may also choose to burn the wart with liquid nitrogen or numb the skin and then scrape off the wart. Another removal process is electrocautery (electric burning), destroying the wart by burning it with an electric needle. **Laser surgery** is also becoming a more common option for removing warts.

Genital warts are the most difficult to treat. They can be removed, but the viral infection itself cannot be cured. Often, because the warts are so small, more than one treatment may be needed. The virus continues to live in the deeper skin, which is why warts often return after they have been removed. Strong chemicals may be applied as well as surgical excision with or without electrocautery. This therapy requires a small operative procedure and a local anesthetic. Laser therapy, although more expensive, is often used for treating venereal warts that are more extensive. The use of lasers which vaporize the lesion can theoretically transmit the HPV. It is not at all clear, however, if this occurs.

There is no one recommended method for eliminating plantar warts. If detected early, cryotherapy is usually enough. However, they can be very resilient, requiring treatment over several months. Treatment ranges from the conservative approach of applying chemical solutions to the more aggressive option of

WWW.BOOKBAZ.IR

surgery. Patients with diabetes or **vascular disease** are usually treated with the more conservative methods.

Alternatives

There are a variety of alternative approaches to the treatment of warts. The suggestions described below apply to common warts and plantar warts, not to genital or cervical warts. Since genital and cervial warts are transmitted sexually, they should be treated by a physician.

For the treatment of common or plantar warts, alternative practitioners may recommend these remedies:

- Apply a paste made of vitamin C powder to the wart for one to two weeks.
- Place a crushed or sliced garlic clove over the wart for seven consecutive nights while sleeping.
- Soak the wart in water, put cross-hatches over it with a sterile needle, and apply drops of thuja (*Thuja occidentalis*) tincture onto the wart. Repeat the cross-hatching and tincture application until the wart is saturated with the tincture. Repeat several times each day for one to two weeks. (A tincture is an herbal extract made with alcohol.)
- Tape a piece of banana peel, smooth side down, over the wart and leave it on overnight. Repeat nightly for one to two weeks.

Because warts are caused by a virus, general immune system support can be effective in helping to keep warts from coming back after treatment or to keep them from multiplying or growing. Eating a well balanced diet high in sources of **vitamins** A, C, and E can help strengthen the immune system. Avoiding **stress**, which is believed to compromise the immune system, is also helpful.

Prognosis

Even though genital warts may be removed, the virus itself continues to live. The HPV can cause tissue changes in the cervix of women with cervical infection. The general recommendation for women who have a history of genital warts is to see their doctors every six months for Pap smears to monitor any changes that may occur.

For plantar warts, the treatment goal is to destroy the wart and its virus without causing much damage to healthy skin. It is not unusual for treatment to cause pain until the foot heals because of the weight put on the foot.

Prevention

Genital warts can be prevented by using **condoms** and avoiding unprotected sex. Barrier protection will not, however, prevent the spread of wart-causing HPV to uncovered areas such as the pubis and upper thighs. Plantar warts can be prevented by wearing shoes, changing shoes daily, keeping feet clean and dry, and not ignoring skin growths and changes in the skin.

Wechsler intelligence test

Definition

The Wechsler Intelligence Scales are a series of standardized tests used to evaluate cognitive abilities and intellectual abilities in children and adults.

Purpose

The Wechsler Intelligence Scales for Children (regular, revised, and third edition) and Wechsler Preschool and Primary Scale of Intelligence are used as

KEY TERMS

Norms—Normative or mean score for a particular age group.

Representative sample—A random sample of people that adequately represents the test-taking population in age, gender, race, and socioeconomic standing.

Standard deviation—A measure of the distribution of scores around the average (mean). In a normal distribution, two standard deviations above and below the mean includes about 95% of all samples.

Standardization—The process of determining established norms and procedures for a test to act as a standard reference point for future test results.

tools in school placement, in determining the presence of a learning disability or a developmental delay, in identifying giftedness, and in tracking intellectual development.

The Wechsler Adult Intelligence Scales (regular and revised) are used to determine vocational ability, to assess adult intellectual ability in the classroom, and to determine organic deficits. Both adult and children's Wechsler scales are often included in **neuropsychological testing** to assess the brain function of individuals with neurological impairments.

Precautions

Intelligence testing requires a clinically trained examiner. The Wechsler scales should be administered, scored, and interpreted by a trained professional, preferably a psychologist or psychiatrist.

Description

All of the Wechsler scales are divided into six verbal and five performance subtests. The complete test takes 60-90 minutes to administer. Verbal and Performance IQs are scored based on the results of the testing, and then a composite Full Scale IQ score is computed. Although earlier editions of some of the Wechsler Scales are still available:

Wechsler Adult Intelligence Scale-Revised (WAIS-IV)

The WAIS-IV, the 2008 revision of the Wechsler Adult Intelligence Scale, is designed for adults, ages 16-74. There are 10 subtests of the WAIS-IV. An example of questions on the subtest of similarities might be: "Describe how the following pair of words are alike or the same—hamburger and pizza." A correct response would be "Both are things to eat."

Wechsler Intelligence Scale for Children, Fifth Edition (WISC-V)

The WISC-V has 15 subtests that include many of the same categories of subtests as the WAIS-IV. Ten subtests are from the previous WISC edition. Five additional subtests cover three core tests and two supplemental tests.

Wechsler Preschool and Primary Scale of Intelligence, Third Edition (WPPSI-III)

The WPPSI is designed for children age 2 years 6 months to 7 months. The test is divided into six verbal and five performance subtests. The 14 subtests are divided into three types: core, supplemental, or optional.

Many insurance plans cover all or a portion of diagnostic psychological testing.

Results

The Wechsler Intelligence Scales are standardized tests, meaning that as part of the test design, they were administered to a large representative sample of the target population, and norms were determined from the results. The scales have a mean, or average, standard score of 100 and a standard deviation of 15. The standard deviation indicates how far above or below the norm the subject's score is. For example, a 10-year-old is assessed with the WISC-III scale and achieves a full-scale IQ score of 85. The mean score of 100 is the average level at which all 10-year-olds in the representative sample performed. This child's score would be one standard deviation below that norm.

While the full-scale IQ scores provide a reference point for evaluation, they are only an average of a variety of skill areas. A trained psychologist will evaluate and interpret an individual's performance on the scale's subtests to discover their strengths and weaknesses and offer recommendations based upon these findings.

Wegener's granulomatosis

Definition

Wegener's granulomatosis is a very rare disease that affects many different organs and systems of the body. It mainly attacks the respiratory system (sinuses, nose, windpipe, and the lungs) and the kidneys. One of the main features of the disease is an inflammation of the blood vessels (**vasculitis**). The inflammation narrows the blood vessels and reduces the blood flow to the affected organs. This destroys tissues and damages vital organs.

Description

Wegener's granulomatosis (WG) is not a contagious disease, and there is no evidence to suggest that it is hereditary either. It is a very rare disease, affecting only 1 in every 30,000–50,000 people. About 500 new cases are diagnosed each year. The disease can occur at any age, however, it mostly affects individuals in their thirties and forties. It affects males and females equally. Ninety-seven percent of all patients are Caucasian, 2% are black, and 1% are of another race.

Causes and symptoms

No viral, bacterial, or other causative agent has yet been identified for WG. It is thought to be an autoimmune disease, meaning that the body's immune system attacks itself—that is, the body's own tissues.

Whenever there is an infection in the body, proteins called antibodies, which are capable of attacking the infectious agent, are formed in the blood. In WG, the antibodies that are formed are directed against the white blood cells of the immune system. They are therefore called "auto-antibodies" (antibodies against one's own body cells). These auto-antibodies bind to the blood cells and forms clumps known as immune complexes. The complexes accumulate in the tissues and the blood vessels, leading to a tumor-like (granulomatous) inflammation of the blood vessels. This slows down the blood flow to the different organs and tissues, causing damage and resulting in the many symptoms of WG.

KEY TERMS

Auto-antibodies—An antibody that is produced in, and reacts with, an antigen in the same person or animal.

Autoimmune disease—Any disease which causes tissue injury due to an immunological reaction of antibodies against the patient's own tissues.

Granulomatous—Chronic inflamed tissue that forms a granular mass.

Immune complexes—Clusters or aggregates of antigen and antibody bound together.

Vasculitis—Inflammation of the walls of the blood vessels.

The symptoms of WG, and the severity of the symptoms, vary from patient to patient. One of the most common features is a chronic runny nose and other cold-like symptoms that do not respond to standard treatment. The cold symptoms gradually worsen and could lead to **sinusitis** (inflammation of the sinuses), middle ear infection (**otitis media**), **cough**, coughing of blood, and inflammation of the lung (pleuritis and **pneumonia**). Other symptoms include **fever**, **fatigue**, loss of appetite, weight loss, joint **pain**, night sweats, change in urine color, and weakness.

Kidney (renal) disease is the most serious development of WG. Patients who do not have renal disease are said to have "Limited Wegener's."

Diagnosis

Early diagnosis is critical for the most effective treatment of the disease. However, there are no specific laboratory tests for WG. Blood tests are used to rule out other causes of the symptoms and to determine which organs are affected. The blood tests often show anemia (low red cell count) and high white blood cell counts. If the kidneys are involved, red blood cells are seen in the urine when viewed under a microscope. Also, blood tests aimed at measuring kidney function may show abnormalities.

Chest x rays are used to determine if the lungs are involved. **Computed tomography scans** (CT scans) of sinuses and lungs, and **kidney biopsy**, are also important tools used in diagnosing WG.

A specific type of antibody called anti-neutrophil cytoplasmic antibody (ANCA) is seen in the blood of about 90% of the patients with WG. The ANCA is a group of antibodies directed against the individual's own white blood cells (namely, the neutrophils). These anti-neutrophil cytoplasmic antibodies are also found in other inflammatory conditions and diseases (such as HIV infection). Although the ANCA test is useful, it cannot be used by itself to make a diagnosis of WG. However, the amount of ANCA in the blood can be measured and correlates well with the progression of the disease. When there is a relapse or a flare-up, the ANCA levels go up. Levels decrease when the disease is controlled by appropriate treatment.

Since there are no definitive laboratory tests for WG, and the initial symptoms of the disease are not very specific, it takes 5–15 months, on average, to make a diagnosis of WG.

Treatment

Cyclophosphamide (Cytoxan), which is an anti-cancer drug, and **corticosteroids**, such as prednisone, are used to treat WG. These are powerful drugs that suppress the immune system. However, they are also toxic and can have serious side effects. The patient has to be watched carefully by the doctors, and the dosage of the drugs has to be adjusted, if needed.

Since the immune system is suppressed while on these drugs, patients are at an increased risk for contracting infections. Vaccinations for flu and pneumonia are recommended.

Prognosis

In the past, approximately 80% of the patients with untreated WG died within a year of contracting the disease and 90% died within two years. In the early 2000s, however, the prognosis has been dramatically improved. With appropriate treatment, patients can survive for much longer periods and lead relatively normal lives.

Approximately 50% of the patients with WG will have a relapse of the disease. This generally happens within two years of stopping the medication, but can occur at any point either during treatment or after stopping treatment. Therefore, it is extremely important that patients continue to see their doctors regularly even after stopping the medications.

Prevention

At present, there are no preventive measures known for Wegener's granulomatosis.

Lata Cherath, PhD

Weight loss drugs

Definition

Weight loss drugs are medications that may help obese individuals lose weight in combination with a low-calorie diet and physical activity.

Purpose

As of 2014, more than 60% of adults in the United States were overweight or obese. Since the 1980s, the number of overweight people has increased steadily and the number of obese people has almost doubled. Excess weight and physical inactivity account for more than 300,000 premature deaths in the United States each year, second only to smoking-related deaths.

Risks from obesity

Overweight and obese people are at higher risk for developing the following problems:

- sleep apnea (interrupted breathing while asleep)
- osteoarthritis (wearing away of the joints)
- high blood pressure
- heart disease
- stroke
- diabetes
- gallbladder disease
- gout (joint pain caused by excess uric acid)
- many common types of cancer

Body mass index (BMI)

The BMI is used to determine whether a person is healthy weight, overweight, or obese. It defines body weight relative to height and, for most adults, correlates with total body fat. In certain cases, such as body builders or elite athletes who have muscle mass that is

WWW.BOOKBAZ.IR

far above average, a high BMI may not be related to excess body fat.

BMI charts are widely available; however, an approximate BMI can be calculated by squaring height (in inches) and dividing by weight, then multiplying that number by 703. The metric formula for the BMI is the weight in kilograms divided by the square of height in meters.

With the exception of very muscular people and certain ethnic groups, BMI is a measure of health:

- 18.5–24.9: healthy
- 25–29.9: overweight
- 30 or above: obese

Generally the higher the BMI the higher the risk of a wide range of health problems, although being underweight also increases risk of ill health; however, excess abdominal fat is an independent risk factor for metabolic and vascular diseases. Men with waists of more than 40 in (102 cm) and women with waists of more than 35 in (89 cm) are at greater risk for health problems.

Prescription weight loss drugs are approved for use only by people with BMIs of 30 or above or those with BMIs of 27 and above who have other risk factors, including at least one or more of the following:

- high blood pressure
- type 2 diabetes
- dyslipidemia (abnormal amounts of fat in the blood)
- sleep apnea

Even short-term weight loss in some obese people has been found to reduce the following:

- blood pressure
- blood cholesterol
- triglycerides (fats)
- insulin resistance (the inability to utilize blood sugar)

Overweight or obese patients who have not lost an average of 1 lb (0.5 kg) per week after at least six months on a balanced low-calorie diet, including increased **exercise** and behavior therapy, may be considered candidates for weight loss drugs.

Description

Weight loss medications are prescribed only as a component of a weight loss program that includes a healthy low-calorie diet and regular physical activity. On average, people on prescription weight loss drugs lose about 5–10% of their original weight. They may lose in the range of 4.4–22 lb (2–10 kg) above what they might have lost following a diet and exercise program alone. Individuals who lose weight initially on a drug tend to continue to respond. However, those who fail to lose 4 lb (2 kg) within the first month on a weight loss medication may be less likely to respond to that particular drug even at an increased dosage. Most over-the-counter weight loss drugs have been found to be ineffective, unsafe, or both. However, in 2007 the U.S. Food and Drug Administration (FDA) approved the drug Alli, a reduced-strength version of the prescription drug Xenical (orlistat), for over-the-counter sale. It is meant to be used in conjunction with a low-fat, low-calorie diet and a regular exercise program. It can help people lose 50% more weight than by dieting alone, according to its manufacturer, GlaxoSmithKline. However, it is not safe for pregnant and breastfeeding women.

Most weight loss occurs within the first six months of drug use, after which the weight levels off or increases. The majority of patients regain the lost weight after discontinuing the medication. Thus, short-term use of weight loss drugs may not be beneficial. However, long-term use of weight loss drugs may help maintain the lower weight. Since **obesity** is a chronic disorder, treatment must be continued for years or for life. Some prescription weight loss drugs are approved by the FDA for use for long-term use. These include orlistat (Xenical), lorcaserin HCL (Belviq), and a combination of phentermine and topiramate (Qsymia). Phentermine (Adipex-P, Oby-Cap, Suprenza, T-Diet, Zantry) and diethylpropion (Tenuate) are FDA-approved for short-term use.

Appetite suppressants (anorexiants)

Most FDA-approved weight loss drugs suppress the appetite by affecting one or more neurotransmitters in the brain that control appetite and mood. Various appetite suppressants increase the secretion of dopamine, norepinephrine, or serotonin or inhibit the reuptake of these neurotransmitters into the nerve cell. Some drugs affect more than one neurotransmitter. These drugs may cause a person to feel less hungry or more satiated.

Other FDA-approved weight loss drugs for short-term use include:

- benzphetamine (Didrex)
- diethylpropion (Tenuate, Tenuate Dospan, Tepanil Ten-Tab), approved in 1959
- mazindol (Mazanor, Sanorex)
- phendimetrazine (Adipost, Bontril PDM, Bontril Slow-Release, Melfiat, Obezine, Phendiet, Phendiet-105, PT 105, Plegine, Prelu-2, X-Trozine), approved in 1982

- phentermine (Adipex-P, Fastin, Ionamin, Obenix, Oby-trim, Phentercot, Phentride, Pro-Fast, Teramine, Zantry, and many more) approved in 1959
- methamphetamine hydrochloride (Desoxyn), approved by the FDA in the mid-1990s based on very little data. Methamphetamine has a very high potential for abuse and should be used only under the supervision of a physician when other weight-loss drugs have failed and weight-loss surgery is not an option.

Lipase inhibitors

In 1999, the FDA approved orlistat (Xenical, the first of a new class of anti-obesity drugs called lipase inhibitors) for long-term use. Orlistat inhibits the pancreatic enzyme lipase that breaks down dietary fat, which in turn decreases the body's absorption of dietary fat by as much as 30%. The undigested fat is excreted in the stool. Orlistat is prescribed for overweight or obese patients who also have high **cholesterol**, diabetes, high blood pressure, or **heart disease**.

Off-label use

Physicians sometimes prescribe drugs for weight loss that are not FDA-approved for that purpose. This is considered off-label use. It is legal for a physician to prescribe a drug for a purpose that does not have FDA approval, but it is illegal for a drug company to advertise an off-label use.

Off-label weight loss drugs include:

- antidepressants, such as bupropion
- the anticonvulsant drugs topiramate and zonisamide
- the diabetes medications metformin, exenatide, and pramlintide

Antidepressants may result in moderate weight loss for up to six months after which the weight usually is regained. Metformin, used to treat type 2 diabetes, is sometimes prescribed off-label for weight loss. However, it can have serious cardiovascular side effects.

Drugs withdrawn from the market

Although effective for long-term weight loss, fenfluramine (Pondimin and others), dexfenfluramine (Redux), and a fenfluramine/phentermine combination (fen/phen) were withdrawn from the market in 1997 after it was found that they caused potentially fatal complications.

In February of 2004, the FDA prohibited the sale of dietary supplements containing ephedrine alkaloids, including ephedra, Ma huang, Sida cordifolia, and pinellia, because of potential complications. These supplements were aggressively marketed for weight control, as well as for energy and sports performance. Although they may affect modest short-term weight loss, these drugs raise blood pressure, **stress** the circulatory system, and have been linked to **heart attack** and **stroke**.

Phenylpropanol amine, a drug mainly used to treat colds and **allergies**, was also taken off the market because young women who were taking it for weight loss had a higher rate of stroke due to bleeding in the brain.

Sibutramine (Merida) was approved by the FDA in 1997 for long-term weight-loss use. The drug was withdrawn from the United States market in 2012 because of increased risk of heart attack and stroke.

Recommended dosage

Dosages of appetite suppressants vary with the individual and the drug prescribed. Some average dosages of appetite suppressants are:

- benzphetamine: 25 to 50-mg tablets once a day in mid-morning or mid-afternoon
- diethylpropion: 25-mg tablets, three times per day, one hour before meals; 75-mg extended-release tablet, once a day in mid-morning
- mazindol: 1-mg tablet once a day, taken with food
- phendimetrazine: 17.5–35-mg tablets, two to three times per day, one hour before meals; 105-mg extended-release capsules, 30 to 60 minutes before the morning meal
- phentermine: 15–37.5-mg capsule or tablet, once a day, before breakfast or one to two hours after or smaller doses 30 minutes before meals; 15–30-mg oral resin capsule, once-per-day, before breakfast
- lorcaserin HCl: 10-mg tablet taken twice daily with our without food
- phentermine/topiramate combination: extended release tabs in combinations of 3.76mg/23mg, 7.5 mg/46 mg, 11.25mg/69mg or 15mg/92mg; one dose taken daily in the morning

The usual dose of prescription orlistat is a 120-mg capsule taken three times a day, up to one hour after each main meal that contains fat. The meal should contain no more than 30% calories from fat. Orlistat should not be taken if a meal is missed, the meal does not contain fat, or it is more than one hour past the meal. The usual dose of Alli, a reduced-strength form of orlistat, is 75 mg.

Precautions

Weight-loss drugs should not be taken by pregnant or **breastfeeding** women.

WWW.BOOKBAZ.IR

With the exception of orlistat, all prescription weight loss medications are controlled substances. Very few studies have evaluated for their safety or effectiveness for periods of more than six months to two years. The use of any combination of weight loss drugs is not recommended. The risks of using appetite-suppressing drugs during **pregnancy** are unknown. Orlistat is approved for use in those aged 12 and above. No other weight loss drug is approved for use in children under age 16.

Many weight-loss drugs are available for sale on the Internet. All weight-loss drugs offered for sale without a prescription have a high probability of being counterfeit, contaminated with other products or illegal. Weight-loss drugs (with the exception of over-the-counter drugs) should be acquired with a physician's prescription, taken only under supervision of a physician, and purchased from a reputable source. Many weight-loss drugs, both legitimate and counterfeit, have serious side effects.

After beginning a weight loss drug, patients should return for follow-ups in two to four weeks, monthly for three months, and then every three months for the first year to monitor weight, blood pressure, pulse, and side effects, and have laboratory testing.

Appetite suppressants

Appetite suppressants should not be taken within 14 days of taking a monoamine oxidase (MAO) inhibitor; extremely high blood pressure and seizures may develop suddenly.

Most appetite suppressants can be habit-forming. In late 2004, Meridia was singled out by critics as a drug that is only minimally effective and has been associated with several deaths.

Amphetamine-type weight loss drugs should not be used by anyone with the following problems:

- high blood pressure
- heart disease
- an overactive thyroid gland
- glaucoma
- pregnant or breastfeeding women

Amphetamine-type weight loss drugs can test positive on urine screenings for amphetamines. This could compromise job seekers who are taking these drugs. These drugs have a high potential for abuse and **addiction**.

Orlistat

Orlistat may decrease the absorption of fat-soluble **vitamins** A, D, and E, and beta-carotene. Therefore, a daily multivitamin supplement, including vitamins A, D, E, and K, should be taken at least two hours before or after orlistat or at bedtime. Foods containing more than 30% fat should be avoided while a person is using orlistat. Gallbladder problems may become worse with orlistat.

Other precautions

Various conditions may affect the choice of a weight loss drug, including the following:

- pregnancy or breastfeeding
- a history of drug or alcohol abuse or dependence
- a history of eating disorders
- a history of depression or manic-depressive disorder
- a family history of mental illness
- the use of MAO inhibitors or other antidepressants
- migraine headaches requiring medication
- glaucoma
- diabetes mellitus
- epilepsy
- thyroid disease
- kidney problems
- gallstones
- liver disease
- problems absorbing food (malabsorption syndrome)
- high blood pressure
- heart disease, a heart condition such as arrhythmia, blood vessel disease
- future surgery that will require general anesthesia

Some dietary supplements are marketed as weight loss products. They are not reviewed by the FDA and are not necessarily safe. They may interact with other drugs and may be dangerous for people with certain medical conditions. Herbal medications have unpredictable amounts of active ingredients and unpredictable and potentially harmful side effects.

Side effects

Many overweight people are generally healthy, and the side effects of weight loss drugs may far outweigh the benefits especially in the short-term. Side effects may be reduced by starting at the lowest effective dose, although any drug can cause an allergic reaction in a susceptible individual.

Appetite suppressants

Side effects appetite suppressants may include:

- increased blood pressure
- dry mouth

- headache
- abdominal cramps or pain
- constipation
- nausea or vomiting
- drowsiness
- insomnia
- irritability
- anxiety
- dizziness, lightheadedness, confusion
- poor coordination

Dry mouth can be relieved with sugarless candy or gum, ice, or a saliva substitute. However, dry mouth lasting more than two weeks can increase the risk of serious dental disease.

Less common side effects of appetite suppressants include:

- fast or irregular heart beat
- skin rash or hives
- fever
- sore throat
- sweating
- uncontrollable trembling or shaking
- diarrhea
- unusual bruising or bleeding
- depression

Other side effects of amphetamines can include:

- addiction
- a false sense of well-being
- an unpleasant taste
- decreased alertness
- restlessness
- uncontrollable activity or excitement
- hallucinations
- increased need to urinate
- difficult or painful urination
- numbness, particularly on one side of the face or body
- blurred vision
- changes in libido or decreased sexual function

Higher dosages, more frequent doses, or longer-term use of amphetamines can lead to physical dependence or overdose, with symptoms that include:

- skin disease
- severe insomnia
- excessive excitability or irritability
- panic
- violent urges
- personality changes
- severe mental illness
- high or low blood pressure
- seizures
- coma

Symptoms of withdrawal may be lessened or prevented by gradually reducing the dosage.

Orlistat

Orlistat side effects usually are mild and can improve with continued use and eating small, low fat meals. They may include the following:

- intestinal discomfort or cramping
- flatulence
- frequent, urgent need to defecate
- inability to control bowel movements and leakage
- oily diarrhea
- flu- or cold-like symptoms
- irregular menstrual periods

Less common side effects of orlistat include:

- rectal pain
- back pain
- tooth or gum problems
- chest tightness
- wheezing
- anxiety

Serious orlistat side effects requiring immediate medical attention include:

- itching, rash, or hives
- fever
- frequent, difficult, or painful urination
- bloody or cloudy urine
- swelling of body parts
- chest pain
- difficulty breathing
- earache or hearing changes

Orlistat side effects can be worsened by eating meals with at least 30% of total calories from fat. Side effects usually disappear within two to three days after discontinuing the drug.

Beviq

Beviq side effects may include the following:

- headache
- back pain

WWW.BOOKBAZ.IR

- dizziness
- fatigue
- nausea
- dry mouth
- constipation
- hypoglycemia in patients with diabetes
- confusion and attention difficulties
- slow heartbeat
- changes in mood

Qsymia

Qsymia side effects may include the following:

- dizziness
- constipation
- dry mouth
- insomnia
- mood disorders including depression
- increase in resting heart rate
- impaired concentration and attention

Interactions

Weight-loss drugs can interact negatively with numerous other drugs. It is important for patients to tell their doctor and pharmacist about all medications, including over-the-counter and herbal medications that they are taking to prevent potentially deadly interactions. Some substances known to interact with weight-loss drugs include the following:

- other appetite suppressants and amphetamines
- caffeine
- cold and allergy medicines
- asthma medications
- selective serotonin reuptake inhibitors (Saris)
- tricycles antidepressants
- medications used during surgical, dental, or emergency procedures
- cocaine and other street drugs
- herbal remedies such as St. John's Wort

ranging from no symptoms or mild flu-like symptoms to encephalitis or **meningitis**. The virus can cross the blood-brain barrier and cause severe illness and **paralysis**.

Description

The primary hosts of WNV are birds, in which the virus numbers multiply before being transmitted by mosquitoes to the next victim. WNV can infect more than 140 species of birds, and can also infect other vertebrates, including humans.

WNV is a flavivirus, belonging to a genus of viruses in the family Flaviviridae. Infections with WNV generally occur between late summer and early fall in temperate areas, and throughout the year in southern climates.

Most mosquitoes can become infected with the WNV. Female mosquitoes of the *Culex pipiens* species are of particular concern. Known as house mosquitoes, these insects live in suburban and urban areas, can survive through the winter, prefer to feed on birds, and frequently bite humans (female mosquitoes require a blood meal to nourish their eggs). While house mosquitoes are also the most common vector for WNV transmission, other common carriers of WNV include *Culex restuan*, *Culex quinquefasciatus*, *Aedes Albopictus*, and *Aedes Vexans*.

Most vertebrates, such as alligators, bats, chipmunks, skunks, squirrels, and rabbits, can also be infected with WNV. Horses, in particular, are commonly infected with WNV. Like humans, the majority of horses suffer either no or mild symptoms, but severe illness and death can and does occur. There are relatively few cases of dogs and cats becoming infected with WNV. When animals do exhibit symptoms of WNV, they include **fever**, weakness, poor coordination, spasms, seizures, and/or behavioral changes.

Origins

WNV was originally isolated in a feverish woman living in the West Nile District of Uganda during 1937, and was linked to severe human meningoencephalitis in elderly patients during a 1957 outbreak in Israel. Outbreaks were sporadic until the mid-1990s when Algeria and Romania reported large numbers of encephalitis due to WNV. Other outbreaks have since followed.

In the summer of 1999, WNV was first reported in the New York City area and then spread rapidly across the entire continent. It is still unknown how WNV reached the United States, but it is suspected

WWW.BOOKBAZ.IR

that the transport of infected birds or the international travel of infected humans may have been to blame. After its arrival in the New York area, the virus quickly made its way across the United States, as well as north into Canada and south into Mexico. In 2012, a severe outbreak of WNV in the United States killed 286 people, the highest number of U.S. casualties for WNV (as of 2014). As of 2014, the Centers for Disease Control and Prevention (CDC) reported that West Nile virus had been detected in all lower 48 states, but not in Hawaii or Alaska.

Demographics

In the United States, the CDC monitors and records human WNV infections. In 2013, 2,469 cases of WNV disease were reported from 47 states and the District of Columbia. More than half (58%) of those with the disease were male. Of the total 2,469, 61% (1,494) were hospitalized, and 119 people died. Deaths were more common among the elderly: The median age of patients who died was 78 years.

Causes and symptoms

Like most flaviviruses, the WNV is maintained in a natural host-vector-host cycle, where a the virus must be transmitted from one infected organism to another (the primary or reservoir host to the next victim) by way of a separate organism (known as the vector). In WNV, the primary vector is the mosquito, which feeds on the reservoir host, usually a bird, and picks up the virus in its blood meal. The virus then multiplies rapidly within the mosquito over the next few days. When the mosquito goes on to feed on another animal, such as a human, it can infect the animal with the virus through its bite.

WNV is not transmitted from person-to-person through touch, kissing, or other contact, but there is evidence of WNV transplacental (mother-to-child) transmission, as well as viral transmission through **breastfeeding**. Because of this risk, pregnant mothers should be aware of the presence of WNV in their area and take appropriate precautions. Due to reports of WNV being transmitted in blood transfusions and organ transplants, the current blood supply is now tested for the presence of the virus. People who are immunocompromised (from disease or **chemotherapy**, for example) and people aged 50 and older represent the highest risk groups for serious WNV infection.

Following infection, the virus enters the host's bloodstream and multiples. The incubation period for WNV after infection typical ranges between three to 14 days. About 80% of infected persons will exhibit no clinically apparent symptoms, and the remaining approximately 20% will exhibit a series of mild flu-like symptoms, also known as West Nile fever. These mild symptoms can persist for three to six days, sometimes lingering for weeks. Symptoms include:

- eye pain
- fever
- headache
- loss of appetite
- lymphadenopathy (abnormal enlargement of the lymph nodes)
- malaise (nonspecific bodily discomfort)
- myalgia (nonspecific muscular pain/tenderness)
- nausea
- rash on the neck, torso, and limbs
- vomiting

Although rare, WNV can cross the blood-brain barrier, which separates the blood from the central nervous system. When this occurs, the virus can infect the brain, spinal cord, and other vital systems, creating a potentially deadly inflammatory response. Immunocompromised and patients older than 50 are at an increased risk for developing more severe illness. In fact, the vast majority of severe illness is among this older population. Symptoms indicating the possible presence of severe West Nile–related syndromes include:

- severe headache
- high fever
- acute muscle weakness
- neck stiffness
- convulsions and tremors
- disorientation and stupor
- paralysis
- coma

Additionally, severe WNV disease can cause acute vision loss due to inflammatory disorders of the eye, such as chorioretinitis, **optic neuritis**, retinal **vasculitis**, **uveitis**, and vitritis. Less frequently, the patient can exhibit acute flaccid paralysis, similar to poliomyelitis (**polio**) or Guillain–Barré syndrome, caused by inflammation of the spinal cord and/or damage to the peripheral nerves. In some severe cases, this acute flaccid paralysis can disrupt muscles that control breathing and result in **respiratory failure**.

Typically, severe WNV syndromes manifest as one of three syndromes: West Nile encephalitis (inflammation of the brain); West Nile meningitis (inflammation of the meninges of the brain and spinal cord); or West Nile meningoencephalitis (inflammation of both the

brain and the meninges). These three syndromes can cause severe brain damage and even death. Severe WNV disease carries a mortality rate ranging between 3% and 15%. The majority of these deaths are a result of complications attributable to West Nile meningoencephalitis. Because of the serious nature of severe WNV syndromes, patients should contact their health provider immediately if they develop a severe **headache** accompanied by high fever.

Diagnosis

A proper diagnosis of WNV infection depends heavily upon detailed clinical presentation to prevent confusion with viral infections, laboratory testing, and patient history. Patients with a known susceptibility to WNV (the elderly and immunocompromised) and who exhibit symptoms during the late spring to early fall, or at any time in warmer climates, should be tested for WNV and other arboviral infections. Additionally, health providers should remain aware of the local presence of WNV activity, such as reports of recent animal and/or human cases.

Symptomatic WNV infection can be classified as either neuroinvasive or non-neuroinvasive. In the former, patients have acutely altered mental status, such as disorientation, stupor, or **coma**, and acute central or peripheral neurological difficulties, such as paralysis, nerve palsy, sensory deficits, and abnormal muscle function. Both neuroinvasive and non-neuroinvasive cases present with a high fever (100.4°F [38°C] or higher).

Verification of WNV includes identification of the virus or viral antibodies in the patient's tissue, blood, or other bodily fluid.

Treatment

As of 2014, there were no treatment modalities for WNV infection. Instead, supportive care is utilized to treat the varying symptoms and syndromes associated with the various West Nile diseases. Although milder symptoms can be treated at home, more severe symptoms may call for hospitalization. Treatment of severe symptoms may require the use of intravenous infusions, airway and respiratory management and support, and use of preventive measures against secondary infection.

Prognosis

The majority of WNV infections will manifest asymptomatically. When symptoms appear, they will usually resolve within a few days (sometimes weeks) with no adverse side effects. The prognosis is not as positive, however, for patients suffering the more severe syndromes attributable to WNV infection. Symptoms of West Nile encephalitis, West Nile meningitis, and West Nile meningoencephalitis can last for several weeks and can cause severe and permanent neurological damage. Inflammation can interfere with the brain and central nervous system and result in death, especially among the elderly population. Patients with West Nile poliomyelitis may suffer prolonged muscle weakness and loss of motor control. Long-term **rehabilitation** is typically required and a full recovery is not assured. If the poliomyelitis affects muscles used for breathing, death from respiratory failure may result.

An economic analysis published in 2014 estimated that the total cumulative costs of reported WNV hospitalized cases in the United States from 1999–2012 was $778 million.

KEY TERMS

Flavivirus—An arbovirus that can cause potentially serious diseases, such as dengue, yellow fever, and West Nile fever.

Guillain-Barré—A disorder in which the body's immune system attacks part of the peripheral nervous system. Weakness, tingling, and abnormal sensations in the arms and upper body can progress until the muscles become totally disabled and the patient is effectively paralyzed.

Meninges—A series of membranous layers of connective tissue that protect the central nervous system (brain and spinal cord). Damage or infection to the meninges, such as in meningitis, can cause serious neurological damage and even death.

Zoonotic diseases—Diseases caused by infectious agents that can be transmitted between (or are shared by) animals and humans. This can include transmission through the bite of an insect, such as a mosquito.

Prevention

Although there is a vaccine used for horses and exotic birds in zoos, there was no WNV vaccine for humans as of 2014, although research on vaccines was under way and pharmaceutical companies had them in development.

Prevention techniques of WNV typically coincide with avoidance measures against mosquito bites, the primary source of the virus. These include the use of

WWW.BOOKBAZ.IR

insect repellant (with N,N-diethyl-meta-toluamide, or DEET) on exposed body parts, wearing loose-fitting clothes over the limbs and torso while outdoors, using mosquito coils and/or citronella candles outdoors, and limiting outdoor activities during peak mosquito-biting periods and/or in areas with high mosquito density. Screen doors and enclosed porches can help keep mosquitoes from coming into the house. While camping outdoors, knockdown spray or bed netting with pyrethrum is suggested.

Removing potential mosquito breeding areas from near the home and from the neighborhood can further reduce the risk of bites. Any container that can collect half an inch of standing water can become a potential breeding site in as little as five days. Old tires, empty plant pots, and empty trashcans should be removed, while water sources such as ponds or birdbaths should be cleaned regularly. Standing water on any property should be drained. This includes clogged eaves. Swimming pools and hot tubs should be properly covered and chlorinated to prevent mosquitoes breeding in them.

In addition, mosquito eradication programs have been instituted in most major cities.

Wheezing

Definition

Wheezing is a high-pitched whistling sound associated with labored breathing.

Description

Wheezing occurs when a child or adult tries to breathe deeply through air passages that are narrowed or filled with mucus as a result of:

- allergy
- infection

- illness
- irritation

Wheezing is most common when exhaling. It is sometimes accompanied by a mild sensation of tightness in the chest. **Anxiety** about not being able to breathe easily can cause muscle tension that makes matters worse.

Causes and symptoms

Wheezing is the symptom most associated with **asthma**. It can be caused by:

- exposure to allergens (food, pollen, and other substances that cause a person to have an allergic reaction)
- fumes
- ice-cold drinks or very cold air
- medication
- strenuous exercise
- weather changes
- foreign objects trapped in the airway
- cystic fibrosis and other genetic disorders
- respiratory illnesses, such as pneumonia, bronchitis, congestive heart failure, and emphysema

Diagnosis

A family physician, allergist, or pulmonary specialist takes a medical history that includes questions about **allergies** or unexplained symptoms that may be the result of allergic reactions. If the pattern of the patient's symptoms suggests the presence of allergy, skin and blood tests are performed to identify the precise nature of the problem.

A pulmonary function test may be ordered to measure the amount of air moving through the patient's breathing passages. X rays are sometimes indicated for patients whose wheezing seems to be caused by chronic **bronchitis** or **emphysema**.

In 2004, researchers in Japan discovered a new method for diagnosing asthma in infants by testing for certain antibodies in their sputum (mucus that spits up from the bronchi).

Treatment

Mild wheezing may be relieved by drinking plenty of juice, water, weak tea, and broth. Ice-cold drinks should be avoided.

A vaporizer can help clear air passages. A steam tent, created by lowering the face toward a sink filled with hot water, placing a towel over the head and sink, and inhaling the steam, can do likewise.

Bronchodilators (medications that help widen narrowed airways) may be prescribed for patients whose wheezing is the result of asthma. Newer asthma medications taken daily can help prevent asthma attacks, as can avoiding asthma and allergy triggers.

Antibiotics are generally used to cure acute bronchitis and other respiratory infections. **Expectorants** (cough-producing medications) or certain bronchodilators are prescribed to remove excess mucus from the breathing passages.

If wheezing is caused by an allergic reaction, **antihistamines** will probably be prescribed to neutralize body chemicals that react to the allergen.

Medical emergencies

Breathing problems can be life-threatening. Immediate medical attention is required whenever an individual:

- turns blue or gray and stops breathing
- becomes extremely short of breath, and is unable to speak
- coughs up bubbly-pink or white phlegm
- seems to be suffocating
- develops a fever of 101°F (38.3°C) or higher
- wheezes most of the time and coughs up gray or greenish phlegm

Alternatives

Certain **yoga** positions (Bridge, Cobra, Pigeon, and Sphinx) may relieve wheezing by improving breathing control and reducing **stress**. Patients whose wheezing is related to asthma, chronic bronchitis, emphysema, or a severe allergic reaction may benefit from these techniques, but must continue to have their condition monitored by a conventional physician.

Prognosis

Mild wheezing caused by infection or acute illness usually disappears when the underlying cause is eliminated.

Some doctors believe that childhood respiratory infections may activate parts of the immune system that prevent asthma from developing.

Prevention

Stopping **smoking** can eliminate wheezing. So can reducing or preventing exposure to other substances that cause the problem.

Whiplash

Definition

Whiplash is a sudden, moderate-to-severe strain affecting the bones, discs, muscles, nerves, or tendons of the neck.

Description

The neck is composed of seven small bones. Known as the cervical spine, these bones:

- support the head
- help maintain an unobstructed enclosure for the spinal cord
- influence the shape and structure of the spine
- affect posture and balance

About 1,000,000 whiplash injuries occur in the United States every year. Most are the result of motor vehicle accidents or collisions involving contact sports. When unexpected force jerks the head back, then forward, the bones of the neck snap out of position, and irritated nerves can interfere with flow of blood and transmission of nerve impulses. Pinched nerves can damage or destroy the function of body parts whose actions they govern.

Risk factors

Osteoarthritis of the spine increases the risk of whiplash injury. So do poor driving habits, driving in bad weather, or driving when tired, tense, or under the influence of alcohol or other drugs.

Causes and symptoms

Tension shortens and tightens muscles. **Fatigue** relaxes them. Either condition increases the likelihood that whiplash will occur and the probability that the injury will be severe.

Sometimes symptoms of whiplash appear right away. Sometimes they do not develop until hours, days, or weeks after the injury occurs. Symptoms of whiplash include:

- pain or stiffness in the neck, jaw, shoulders, or arms
- dizziness
- headache
- loss of feeling in an arm or hand
- nausea and vomiting

Depression and vision problems are rare symptoms of this condition.

Diagnosis

Whiplash is difficult to diagnose because x rays and other imaging studies do not always reveal changes in bone structure. Organs affected by nerve damage or reduced blood supply may generate symptoms not clearly related to whiplash.

Diagnosis is based on observation of the patient's symptoms, medical history, **physical examination**, and neurological studies to determine whether the spine has been injured.

Treatment

Medication, **physical therapy**, and supportive measures are used to treat whiplash. Chiropractors gently realign the spine to relax pinched nerves or improve blood flow. A patient whose symptoms are severe may wear a soft, padded collar (Thomas collar or cervical collar) until the **pain** diminishes.

When pressure on the root of the nerve causes loss of strength or sensation in a hand or arm, a cervical **traction** apparatus may be recommended.

Self-care

Inflammation and cramping can be alleviated by wrapping ice or an ice pack in a thin towel and applying it to the injured area for 10-20 minutes every hour. After the first 24 hours, painful **muscle spasms** can be prevented by alternating cold packs with **heat treatments**. Letting a warm shower run on the neck and shoulders for 10-20 minutes twice a day is recommended. Between showers, warm towels or a heat lamp should be used to warm and soothe the neck for 10-15 minutes several times a day.

Improving posture is important, and gentle massage can be beneficial. Sleeping without a pillow promotes healing, and a cervical collar or small rolled towel pinned under the chin can provide support and prevent muscle fatigue.

Alcohol should be avoided. A chiropractor, primary care physician, or orthopedic specialist should be notified whenever a painful neck injury occurs. Another situation requiring attention is if the face or arm weaken or become painful or numb following a neck injury.

Prognosis

With treatment, whiplash can usually be cured in one week to three months after injury occurs. If nerve roots are damaged, numbness and weakness may last until recovery is complete.

Prevention

Chiropractors can recommend diet and **exercise** techniques to reduce **stress** and tension. Careful, defensive driving, wearing seatbelts, and using padded automobile headrests can lessen the likelihood of whiplash.

Whipple's disease *see* **Malabsorption syndrome**

White blood cell count and differential

Definition

A white blood cell (WBC) count determines the concentration of white blood cells in the patient's blood. A differential determines the percentage of each of the five types of mature white blood cells.

Purpose

A WBC count is included in general health examinations and to help investigate a variety of illnesses. An elevated WBC count occurs in infection, allergy, systemic illness, inflammation, tissue injury, and leukemia. A low WBC count may occur in some viral infections, **immunodeficiency** states, and bone marrow failure. The WBC count provides clues about certain illnesses, and helps physicians monitor a patient's recovery from others. Abnormal counts that return to normal indicate that the condition is improving, while counts that become more abnormal indicate that the condition is worsening. The differential will reveal which WBC types are affected most. For example, an elevated WBC count with an absolute increase in lymphocytes having an atypical appearance is most often caused by **infectious mononucleosis**. The differential will also identify early WBCs, which may be reactive (e.g., a response to acute infection) or the result of a leukemia.

KEY TERMS

Band cell—An immature neutrophil at the stage just preceding a mature cell. The nucleus of a band cell is unsegmented.

Basophil—Segmented white blood cell with large dark blue-black granules that releases histamine in allergic reactions.

Cytoplasm—The part of a cell outside of the nucleus.

Differential—Blood test that determines the percentage of each type of white blood cell in a person's blood.

Eosinophil—Segmented white blood cell with large orange-red granules that increases in response to parasitic infections and allergic reactions.

Lymphocyte—Mononuclear white blood cell that is responsible for humoral (antibody mediated) and cell mediated immunity.

Monocyte—Mononuclear phagocytic white blood cell that removes debris and microorganisms by phagocytosis and processes antigens for recognition by immune lymphocytes.

Neutrophil—Segmented white blood cell normally comprising 50%–70% of the total. The cytoplasm contains both primary and secondary granules that take up both acidic and basic dyes of the Wright stain. Neutrophils remove and kill bacteria by phagocytosis.

Nucleus—The part of a cell that contains the DNA.

Phagocytosis—A process by which a white blood cell envelopes and digests debris and microorganisms to remove them from the blood.

Description

White cell counts are usually performed using an automated instrument, but may be done manually using a microscope and a counting chamber, especially

WWW.BOOKBAZ.IR

when counts are very low, or if the patient has a condition known to interfere with an automated WBC count.

An automated differential may be performed by an electronic cell counter or by an image analysis instrument. When the electronic WBC count is abnormal or a cell population is flagged, meaning that one or more of the results is atypical, a manual differential is performed. The WBC differential is performed manually by microscopic examination of a blood sample that is spread in a thin film on a glass slide. White blood cells are identified by their size, shape, and texture.

The manual WBC differential involves a thorough evaluation of a stained blood film. In addition to determining the percentage of each mature white blood cell, the following tests are preformed as part of the differential:

- An evaluation of RBC morphology includes grading of the variation in RBC size (anisocytosis) and shape (poikilocytosis); reporting the type and number of any abnormal or immature RBCs; and counting the number of nucleated RBCs per 100 WBCs.
- An estimate of the WBC count is made and compared with the automated or chamber WBC count. An estimate of the platelet count is made and compared with the automated or chamber platelet count. Abnormal platelets, such as clumped platelets or excessively large platelets, are noted on the report.
- Any immature WBCs are included in the differential count of 100 cells, and any inclusions or abnormalities of the WBCs are reported.

Precautions

Many medications affect the WBC count. Both prescription and non-prescription drugs, including herbal supplements, should be noted. Normal values for both the WBC count and differential are age-related.

Sources of error in manual WBC counting are due largely to variance in the dilution of the sample and the distribution of cells in the chamber, as well as the small number of WBCs that are counted. For electronic WBC counts and differentials, interference may be caused by small fibrin clots, nucleated red blood cells (RBCs), platelet clumping, and unlysed RBCs. Immature WBCs and nucleated RBCs may cause interference with the automated differential count. Automated cell counters may not be acceptable for counting WBCs in other body fluids, especially when the number of WBCs is less than 1,000 per microliter (μμL) or when other nucleated cell types are present.

Preparation

This test requires a 3.5 mL sample of blood. Vein puncture with a needle is usually performed by a nurse or phlebotomist, a person trained to draw blood. There is no restriction on diet or physical activity.

Aftercare

Discomfort or bruising may occur at the puncture site. Pressure to the puncture site until the bleeding stops reduces bruising; warm packs relieve discomfort. Some people feel dizzy or faint after blood has been drawn and should be allowed to lie down and relax until they are stable.

Risks

Other than potential bruising at the puncture site, and/or **dizziness**, there are no complications associated with this test.

Results

Normal values vary with age. White blood cell counts are highest in children under one year of age, and then decrease somewhat until adulthood. The increase is largely in the lymphocyte population. Adult normal values include:

- WBC count: 4,500–11,000/μμL
- polymorphonuclear neutrophils: 1800–7800/μμL; (50%–70%)
- band neutrophils: 0–700/μμL; (0%–10%)
- lymphocytes: 1,000–4,800/μμL; (15%–45%)
- monocytes: 0–800/μμL; (0%–10%)
- eosinophils: 0–450/μμL; (0%–6%)
- basophils: 0–200/μμL; (0%–2%)

Mark A. Best
REVISED BY ROSALYN CARSON-DEWITT, MD

KEY TERMS

Electrolytes—Salts and minerals that ionize in body fluids. Common human electrolytes are sodium, potassium, calcium, chloride, and bicarbonate. Electrolytes control the fluid balance of the body and are important in muscle contraction, energy generation, and almost any major biochemical reaction in the body.

Saline—A salt water solution that approximates the concentration of sodium and chloride in the blood.

Whole-bowel irrigation

Definition

Whole-bowel irrigation is performed to clean out the bowels. It involves the administration of a special solution, often polyethylene glycol, either by drinking or through a nasogastric tube placed into the stomach. The solution prompts very voluminous liquid diarrhea; the goal of whole-bowel irrigation is to cleanse the bowel prior to surgery or other medical procedure or to rid the stomach of ingested poisons, toxins, or drug packets.

Description

If prepping for surgery or medical study patients usually drink the solution at home. Whole-bowel irrigation may be performed in a hospital emergency department or intensive care unit as ordered by an emergency room physician or gastroenterologist. While the solution can be swallowed, most individuals find it difficult to take in the large volume necessary for whole-bowel irrigation. In this case, a nasogastric tube is inserted, and the solution is instilled directly through the tube into the stomach. The procedure is repeated until the stool that is passed is clear.

Purpose

At one time, whole-bowel irrigation was common practice to remove certain poisons. The procedure is now mostly done as preperation for surgery, colonoscopy, or certain x-ray studies. Recent thinking by the American Academy of Clinical Toxicology is that whole-bowel irrigation should not be used routinely with poisoned patients. It is useful only if the patient has swallowed a life-threatening quantity of poison, and when the irrigation can be done within 60 minutes after the poison was swallowed. Some of the substances for which whole-bowel irrigation can be useful include heavy metals (such as lithium), as well as enteric-coated or sustained-release tablets.

Preparation

Little preparation is necessary for this procedure other than educating the patient as to what will happen. The patient should remove dental appliances before a nasogastric tube is inserted.

Aftercare

After whole-bowel irrigation, the patient's vital signs will be monitored. Checks will be made for fluid and electrolyte imbalances. If necessary, additional treatment to prevent gastrointestinal bleeding or poisoning will be done.

Results

The patient passes stool that becomes increasingly clear, and eventually shows no solids or color. Whole-bowel irrigation is usually tolerated by patients and is a temporary treatment, performed in conjunction with other therapies.

Risks

In poisoning cases, whole-bowel irrigation delays the administration of activated charcoal, which may be more beneficial to treating the patient than flushing the stomach. In addition, whole-bowel irrigation may stimulate bleeding from the esophagus or stomach. The patient may inhale some of the stomach contents, causing aspiration, pneumonia, or infection in the lungs. Fluid and electrolyte imbalances are more likely to occur in older, sicker patients. Mechanical damage to the throat is more likely in patients who are uncooperative.

WWW.BOOKBAZ.IR

Other conditions that prevent the use of whole-bowel irrigation include any kind of intestinal blockage, significant bleeding within the gastrointestinal tract, low blood pressure or low cardiac output, and uncontrollable vomiting.

Whooping cough

Definition

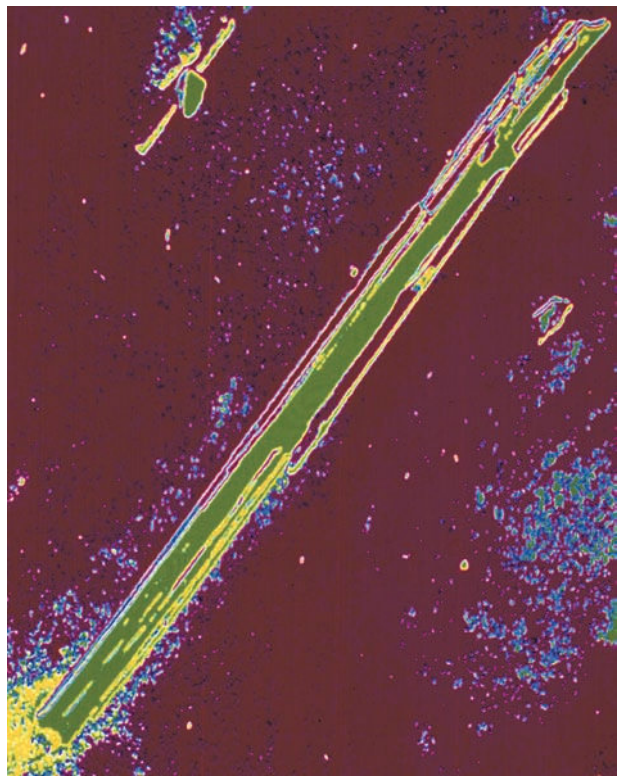
Whooping **cough**, also known as pertussis, is a highly contagious bacterial disease that causes spasms (paroxysms) of uncontrollable coughing, followed by a sharp, high-pitched intake of air that creates the characteristic whoop of the disease's name.

Description

Whooping cough is caused by the bacterium *Bordatella pertussis*, which was first identified by the French scientists Jules Bordet and Octave Gengou in 1906. *B. pertussis* causes its most severe symptoms by attaching itself to ciliated cells in the respiratory tract. Cilia are small, hair-like projections that beat continuously to sweep the respiratory tract clean of mucus, bacteria, viruses, and dead cells. When *B. pertussis* interferes with this normal janitorial function, mucus and cellular debris accumulate, causing constant irritation and triggering coughing and increased mucus production.

Risk factors

The primary risk factor for whooping cough is exposure to the bacterium by children who have not been previously exposed or have not completed a full course of the pertussis vaccine. Because the vaccine cannot be administered to infants less than two months of age, newborns are at risk if their mothers have not passed down antibodies against the bacterium. People are also at risk from exposure more than 12 years has passed since they were immunized. Finally, even fully immunized children may be at risk during outbreaks of the disease.



A magnified image of a pertussis toxin crystal that causes whooping cough. *(Custom Medical Stock Photo, Inc.)*

Demographics

Whooping cough is common throughout the world, especially among children. The World Health Organization (WHO) estimates that there are about 16 million cases worldwide annually—95% of them in developing countries—and about 195,000 children die of the disease each year. Although people of any age can contract whooping cough, children under the age of two are at the highest risk for both the disease, and for serious complications and death. This is apparently because exposure to the disease earlier in life affords a degree of immunity, with subsequent infections resembling a **common cold**.

Before pertussis immunizations became routine in the United States in the 1940s, whooping cough was one of the most common childhood diseases and a major cause of childhood mortality. It remains one of

the most poorly controlled vaccine-preventable diseases in the United States and throughout the developed world. Although the number of reported cases varies annually, the incidence of whooping cough increased steadily between 1980s and the early 2000s, with peaks every three to five years. There were 28,639 reported cases in the United States in 2013, according to the Centers for Disease Control and Prevention (CDC). In 2012, the number was 48,277, which was the highest number of reported cases since 1955, when the total was 62,786 cases reported cases. Statistic totals were not yet available for 2014, but as of August 2014, the CDC reported a 30% rise in reported cases over the same period in 2013. Since the majority of cases are not reported, the actual number of cases in the United States is actually much higher, according to the CDC.

Whooping cough is also on the increase in other developed countries, including the United Kingdom where it had previously been nearly eradicated. Although most cases are in infants and children, the largest increases have been among older children and adults.

Much of the blame for increasingly frequent whooping cough outbreaks has been attributed to parents refusing or delaying their children's vaccinations out of misplaced fears about vaccine safety. In the first five months of 2012, for instance, almost 2,300 cases were reported in the state of Washington—13 times more than over the same period in 2011. **Public health** officials blamed the increase on low childhood **vaccination** compliance throughout the Northwest. A 2013 study in New York state found that almost twice as many parents requested religious exemptions from childhood vaccinations in 2011, compared with 12 years earlier. The study found that unvaccinated children were 14 times more likely to contract whooping cough; however, counties with higher exemption rates also reported higher rates of whooping cough among vaccinated children. Some evidence suggests that the pertussis vaccine, while safer than the older vaccine and with fewer side effects, appears to be less effective and less long-lasting. There is also some evidence that pertussis bacterial strains are evolving to evade the vaccine.

Causes and symptoms

B. pertussis is usually transmitted through the air. Coughing or sneezing by an infected person releases droplets containing bacteria that can be inhaled by others. Infants often become infected by family members or caregivers who may not know that they are infected. Someone with whooping cough can easily transmit the infection to 12–15 other people.

Whooping cough has four partially overlapping stages: incubation, catarrhal, paroxysmal, and convalescence (described below). The disease is contagious from the start of the catarrhal stage through the third week after paroxysmal onset or five days after the start of an effective antibiotic.

During the asymptomatic incubation period of seven to 14 days after infection, the bacteria multiply and penetrate tissues lining the entire respiratory tract. This is followed by the catarrhal stage, which is often mistaken for a bad cold. Symptoms include tearing, sneezing, congestion, very runny nose (rhinorrhea), **fatigue**, poor appetite, and mild cough or **fever** lasting seven to 14 days.

The paroxysmal stage, lasting two to four weeks, is characterized by spasms of uncontrollable coughing and the whooping sound made by the sharp inspiration of air after coughing has emptied the lungs. The whoop is thought to be due to inflammation and mucus that narrow the breathing tubes, making it difficult to get air into the lungs. Coughing can be violent enough to cause **choking** or **vomiting**. Paroxysms can be induced by activity, feeding, crying, or even hearing someone else cough. The mucus produced during the paroxysmal stage is thicker and more difficult to clear than the more watery mucus of the catarrhal stage, and patients become increasingly exhausted from attempting to clear the respiratory tract. Infants may have minimal or no coughing; rather, they have life-threatening pauses in breathing called apnea.

Severely ill children may have great difficulty maintaining adequate oxygen levels; they may turn somewhat blue (cyanotic) after a paroxysm due to low oxygen in the blood. These children may suffer brain swelling and degeneration (**encephalopathy**) and seizures, which are believed to be caused both by lack of oxygen to the brain and by bleeding in the brain caused by increased pressure induced by coughing. Some children experience greatly increased abdominal pressure during coughing fits, resulting in hernias (abnormal protrusion of the intestine through a weak area of muscle). Children with whooping cough are also at risk for secondary infections such as **pneumonia**.

Recovery occurs gradually during the convalescent stage, usually over three to four weeks. However, coughing spasms may continue for months, especially if the patient contracts a cold or other respiratory infection.

Diagnosis

Examination

The physician will conduct a physical exam and take a medical history, including information about

WWW.BOOKBAZ.IR

immunizations and any known exposure to whooping cough. Diagnosis based on symptoms can be difficult, however, because in the catarrhal stage whooping cough looks much like a cold, flu, or **bronchitis**. In the paroxysmal stage, whooping cough resembles viral respiratory infections or **tuberculosis**. Thus, as many as 90% of whooping coughs are never diagnosed, especially in adults.

Tests

B. pertussis can be cultured (grown in the laboratory) from mucus swabbed from the nose or throat and identified under a microscope. Blood tests may show an increase in white blood cells indicating inflammation or infection. New diagnostic tests that identify specific bacterial DNA sequences are now being applied to *B. pertussis*. Polymerase chain reaction assays, for instance, amplify even small amounts of DNA for identification, which is especially useful for patients who lack the typical symptoms. These tests have improved diagnosis and may account for some of the increase in the reported incidence.

Procedures

A chest x ray may be performed to determine the severity of the infection.

It is very important to initiate treatment as soon as possible, especially in infants. Symptoms may be reduced if treatment starts at least one week before the onset of paroxysms. For infants and others whose symptoms and exposure are suggestive of whooping cough and are at risk for severe disease, treatment should be initiated without awaiting test results. About half of all babies under one year-of-age with whooping cough require hospitalization.

Treatment

In its early stages, whooping cough is treated with **antibiotics**: azithromycin for infants under one month and trimethoprim-sulfamethoxasole for those over two months of age. Some *B. pertussis* strains have developed resistance to erythromycin. Antibiotics at later stages will not alter the course of the disease. Over-the-counter cough medicines have little effect and are not recommended.

Supportive treatment includes careful monitoring of fluids to prevent **dehydration**, rest in a quiet, dark room to decrease paroxysms, and suctioning of mucus. Sitting up during coughing attacks may help. Other remedies that may be useful include:

- dietary supplements, including vitamins A and C, beta-carotene, acidophilus, lung glandulars, garlic, and zinc
- dietary changes, including drinking plenty of fluids, eating fruits, vegetables, brown rice, whole-grain toast, vegetable broth, and potatoes, and avoiding dairy products
- orange and lemon or carrot and watercress juices
- hydrotherapy—application of wet cloths to the head or chest to relieve congestion
- aromatherapy with essential oils of tea tree, chamomile, basil, camphor, eucalyptus, lavender, peppermint, or thyme

Alternatives

Alternative and complementary therapies may help reduce symptoms and speed recovery but should never replace appropriate antibiotic treatment. Various herbal remedies may help support antibiotic treatment, but before beginning to take any supplements or remedies, patients should consult their doctors. Some patients have found osteopathic manipulation to decrease cough severity and discomfort.

Prognosis

Most people recover from whooping cough with some degree of immunity. Once the cilia and cilia-bearing cells of the respiratory tract are damaged during initial infection, however, the process cannot be reversed with antibiotics, and the patient will undergo the complete progression of symptoms. Symptoms improve with time as the damaged cells are replaced.

Approximately two-thirds of infants hospitalized with whooping cough have slowed or halted breathing, and one-fourth develops pneumonia. Pertussis is fatal in 1–2% of hospitalized infants. Children who die of whooping cough usually suffer from one or more of the following:

- severe pneumonia, possibly accompanied by encephalopathy
- extreme weight loss, weakness, and metabolic abnormalities due to persistent vomiting during paroxysms
- pre-existing conditions, such as low birth weight, poor nutrition, measles, or other respiratory or gastrointestinal infections or diseases

Prevention

The mainstay of whooping cough prevention is immunization beginning at two months of age. In the United States, children receive five doses of DTaP, a combination vaccine that protects against **diphtheria** (D), **tetanus** (T), and whooping cough (aP). The upper-case letters indicate full-strength doses, and "aP" stands for acellular pertussis, meaning that it

contains only part of the *B. pertussis* bacterial cell. DTaP is usually administered at two, four, six, and 15–18 months and four to six years-of-age. Between ages 11 and 13, children may be given a Tdap booster, which has lower doses of pertussis and diphtheria vaccines. Older teens and adults should receive a one-time Tdap booster. Tdap vaccines, which have been licensed since 2005, appear to fully protect about 70% of people from whooping cough.

Infants less than two months cannot be vaccinated against whooping cough, which makes them vulnerable to the illness unless they obtained maternal antibodies in the womb. For this reason, guidelines call for women to receive Tdap during the third trimester of each **pregnancy**. Doing so not only provides maternal antibodies for the newborn, but also protects the mother from whooping cough that she could transmit to her newborn. Everyone in contact with the newborn should also be immunized. Studies indicate that about 80% of infants with whooping cough were infected by household members and 30–40% by their mothers.

The aP vaccine is made with only two to five *B. pertussis* proteins, rather than with the entire killed bacterial cell that was used for the earlier vaccine, which phased out in the late 1990s. The aP vaccine has far fewer side effects, such as high fever and discomfort at the injection site. It appears, however, to be less effective than the older vaccine and offers a shorter period of protection. Researchers have experimented with new adjuvants that can boost the immune response to the aP vaccine. Because whooping cough is so contagious, even fully immunized people can become infected if *B. pertussis* is circulating in the community. For this reason, family members of a patient with whooping cough may be treated with prophylactic antibiotics.

Although there is high pertussis vaccine coverage in children across the United States, protection decreases over time. A 2013 survey found that only 20% of American adults had received the pertussis vaccine within the past 10 years. In 2011, the U.S. Food and Drug Administration approved Boostrix as a single-dose Tdap booster for those aged 65 and older.

Because less than 13% of adults have received a Tdap booster, it is not yet known whether so-called "herd immunity" helps protect against whooping cough. Herd immunity occurs when a sufficient proportion of a population is immune to a disease—either through vaccination or previous infection—such that the infection has little opportunity to spread, and infants and others without immunity are generally protected.

KEY TERMS

Adjuvant—A substance added to vaccines to stimulate a stronger immune response.

Antibodies—Specific proteins produced by the immune system in response to a specific foreign protein or particle called an antigen.

Apnea—Transient halting of breathing.

Booster—A supplementary dose of an immunizing agent.

Bordetella pertussis*; *B. pertussis—The bacterium that causes whooping cough.

Catarrhal stage—The first stage of whooping cough illness, during which the mucous membranes of the respiratory system become inflamed and produce excessive secretions.

Cilia—Tiny, hair-like projections from a cell; cilia in the respiratory tract beat continually to move mucus and debris up and out of the respiratory tree to protect the lung from irritation and infection.

DTaP—A full-strength diphtheria, tetanus, and acellular pertussis combination vaccine.

Encephalopathy—Swelling and degeneration of the brain.

Herd immunity—Community immunity; disease protection for non-immune or unvaccinated individuals that is conferred by the prevailing immunity within a population due to widespread vaccination coverage.

Outbreak—A sudden increase in the incidence of a disease.

Paroxysm—A sudden attack or spasm.

Paroxysmal stage—The violent coughing stage of whooping cough.

Pertussis—Whooping cough.

Prophylactic—Protective measures to prevent an otherwise likely outcome.

Tdap—A full-strength tetanus and reduced-strength diphtheria and acellular pertussis combination vaccine.

Because whooping cough is so contagious, it is important that infected people practice good cough etiquette:

- covering the mouth and nose with a tissue or upper arm when coughing and sneezing
- properly discarding used tissues

WWW.BOOKBAZ.IR

- washing hands thoroughly after coughing or sneezing by using soap and water or hand sanitizer containing at least 60% alcohol

Wilderness medicine

Definition

Wilderness medicine encompasses the prevention, diagnosis, and treatment of injuries and medical conditions that may occur during activities in remote territories.

Purpose

Activities that may require wilderness medicine include backpacking, cross-country skiing, mountaineering, white water rafting, scuba diving, and exploration in undeveloped regions such as deserts or jungles. Wilderness medicine has evolved to deal with situations in which definitive medical care is hours or days away, and in which patients may require quick or extended attention. Wilderness medicine utilizes **first aid** techniques, but requires additional skills that take into account demanding environments, uncommon threats to health, hazardous or lengthy travel to medical facilities, and difficulties in obtaining food, water, and shelter.

Wilderness medicine uses techniques to assess and treat a variety of conditions and injuries, including:

- wounds and burns
- external and internal bleeding
- cardiac arrest
- head injuries
- spinal cord injuries
- fractures and dislocations
- altitude sickness
- problems from cold and heat
- allergic and anaphylactic reactions
- lightning strikes
- near drowning
- insect reptile, and animal bites
- poisoning
- emergency child birth

Precautions

In wilderness situations caregivers should follow the maxim of *first, do no harm*. Uninjured members of groups should not attempt rescues that place themselves in danger. People administering first aid or wilderness medicine should remain calm and organized at all times. Only those with experience should administer medications and medical procedures. Injured people should not be moved until they are fully evaluated or unless environmental conditions are threatening and require immediate shelter.

People with certain medical conditions should avoid travel in the wilderness, which can make existing conditions worse. These conditions include metastatic cancer, peptic **ulcers**, **coronary artery disease**, **chronic obstructive pulmonary disease**, clotting or bleeding disorders, high-altitude sickness, chronic **rheumatoid arthritis**, chronic severe back **pain**, and chronic knee and hip joint disease.

Description

The first stage of wilderness medicine begins with an assessment of the injury or condition. Primary assessment is used to quickly determine if a patient is in a life-threatening situation and to provide immediate emergency care. Secondary assessment is the thorough evaluation of a patient after life-threatening circumstances are relieved.

Primary assessment

A rule of thumb for the first steps of primary assessment, recommended by the Wilderness Medicine Institute, is the ABCDE procedure. It stands for Airway, Breathing, Circulation, Disability, and Exposure assessment. First, a patient's airway should be checked by close observation of whether or not air can move in and out and any obstructions to breathing should be alleviated. In unconscious people the tongue can often fall to the back of the throat and block breathing, so the head should be tilted back and the lower jaw raised to alleviate the obstruction. If neck or spinal cord injuries are suspected, the head must be handled with extreme care to avoid further injury to the delicate spinal cord. In these cases, the lower jaw can be pulled forward to open the airway. If the neck is severely out of alignment due to an injury or fall, it may be gently realigned to free the airway.

After the airway is cleared and breathing is ensured, a patient's circulation is checked by noting the pulse of the carotid artery, on the neck, the pulse of the femoral artery in the front groin, and by listening to the heartbeat. If pulse is lacking, **cardiopulmonary resuscitation** (CPR) may be required, which requires chest compression and mouth-to-mouth breathing. Circulation checks include surveying a patient for bleeding. If severe bleeding is present, it should be stopped by direct pressure to the injured area and by elevating the wound level to the heart, if possible.

Disability assessment means checking for damage to the spinal cord, particularly in the cervical region of the neck. Assessment of exposure determines if environmental conditions, such as heat or cold, are immediate threats to a patient's life, which may require actions such as seeking shelter or covering the patient with protective clothing.

Secondary assessment

During this stage, a thorough **physical examination** of the patient is made from head to toe to determine the extent of injuries or problems. Caretakers performing the assessment should write detailed notes in order to inform physicians or emergency

WWW.BOOKBAZ.IR

workers later. Patients are thoroughly interviewed to determine the scope of problems and any previous medical issues that might be related. Patients should be spoken to calmly to determine their mental states and how well they respond to stimuli. Vital signs such as heart rate and respiration rate should be noted and monitored. The skin should be carefully observed for injuries, **boils**, **rashes**, and discoloration. Red or flushed skin may indicate **fever** or heat-related conditions, while pale or blotchy skin can point to **shock** or **hypothermia**. A bluish tint to the skin may mean a lack of oxygen. **Contact lenses** should be removed from patients in cold conditions, as they can freeze to the eyes. During secondary assessment the patient should be closely monitored over time until improvement is noted or further treatment decisions are made. At all times in wilderness injuries, shock must be watched for and immediately treated.

Shock

In wilderness situations shock should be suspected after traumatic injuries, significant loss of blood due to internal or external bleeding, extreme loss of fluids from **vomiting** or **diarrhea**, heart attacks, and spinal cord injuries. Shock is easiest to alleviate when it is treated early; when not treated properly, it can progress to unconsciousness and death. When the likelihood of shock occurs, patients should be continually monitored and supported.

Symptoms of shock begin with **anxiety** and restlessness, with increased heart rates and labored, shallow breathing. Shock victims tend to sweat profusely with cool and clammy skin. Thirst and nausea are also symptoms.

Shock is treated in the wilderness by maintaining an open airway for the patient to breathe, by treating any injuries such as bleeding **wounds**, by reducing pain if possible, and by replenishing fluids. Patients should be kept calm and warm, and their feet should be elevated if possible to increase blood flow to the organs. If shock symptoms progress, plans should be quickly made to get help or evacuate the patient.

Evacuation

Evacuation of a patient may be a crucial decision in the wilderness, depending upon the severity of an injury or condition, the difficulty of moving the patient, the time considerations involved, and the availability of outside help. In general, if a patient with severe symptoms is not improving despite care then evacuation becomes necessary. The Wilderness Medical Society lists symptoms that require postponing travel or evacuating patients:

- progressive deterioration with symptoms of dizziness, fainting, abnormally slow (bradycardia) or fast (tachycardia) heart rate, labored breathing, poor mental status, progressive weakness, constant vomiting or diarrhea, intolerance of oral fluids, or recurrent loss of consciousness due to head injuries
- debilitating pain
- inability to sustain pace due to medical problems
- passage of blood by mouth or rectum
- symptoms of serious high-altitude illness
- infections that get worse despite treatment
- chest pain that is not musculoskeletal in origin
- psychological status threatening the individual or group

If a patient cannot be moved without risk of further injury, then other members of a party, preferably two or more, should be sent to get outside help. When requesting outside assistance, the safety of incoming rescuers and time constraints should be weighed. Requests for outside help should be made in writing, and include an assessment of the patient and situation as well as a detailed location of the incident. In some regions, helicopter evacuation may be an option, and should be used if an injury is life-threatening.

During evacuation patients must be handled with extreme care, as well as insulated from heat, cold, and further injuries. Larger wilderness expeditions may have special devices available for transporting injured members, while smaller parties may have to improvise transporting devices by using backpacks, ropes, and other available materials.

Wounds and burns

In wilderness situations wound management strives to stop bleeding, prevent infection, and speed healing. Bleeding from wounds should be controlled by direct pressure. Wounds and **burns** should be cleaned gently and thoroughly, treated with antibiotic ointment, and covered with bandages to avoid infections. Wounds that have high risks of infections, such as large cuts, open **fractures**, and animal bites, should be watched closely.

External and internal bleeding

External bleeding should be stopped by direct pressure, such as firmly applying a clean bandage or compress to an open wound. Secondary pressure may be applied to pressure points, such as the large arteries in the upper arm or groin, to slow bleeding. Tourniquets

are recommended only in life-threatening situations, as they can cause complications and infections. Symptoms of internal bleeding include **dizziness**, **fainting**, rapid heartbeat, weak pulse, **shortness of breath**, thirst, loss of color, vomiting blood, blood in the feces or urine, and severe pain or swelling in the abdomen. If internal bleeding is suspected, medical help should be sought immediately. With all cases of significant blood loss, shock must be carefully considered.

Cardiac arrest

Cardiac arrest in the wilderness may require CPR, although CPR is less effective in remote regions that lack access to the **life support** technology that ambulances quickly supply. CPR should be administered to patients who have suffered near **drowning**, hypothermia, lightning strikes, and drug overdoses. CPR generally should not be administered in the wilderness if it endangers the rescuers, if the time of the cardiac arrest is unknown, if the patient appears to be dead or rigor mortis has set in, or if cardiac arrest was caused by severe **trauma** or lethal injuries.

Head injuries

Head injuries that do not cause loss of consciousness in the victim are rarely dangerous. Short-term loss of consciousness following head injuries is known as **concussion**, and these patients should be closely monitored for 24 hours, including waking them every three hours during sleep to check for mental alertness. For head injuries that cause prolonged unconsciousness, the airway and cervical spine must be protected. Severe brain injury is indicated by relapses into unconsciousness, bad headaches, bleeding from the ears, clear fluid draining from the nose, vomiting, persistent disorientation, personality changes, seizures, irregular heartbeat and breathing, and unequal or unreactive pupils. Severe head injuries must be treated by seeking immediate medical help or evacuation.

Spinal cord injuries

If spinal cord injuries are suspected, patients must be immobilized. Some expeditions or rescue teams may carry special splints or vests in their medical kits. If no such equipment is available, *spineboards* may be fashioned from available materials, such as backpacks, poles, or ice axes, to prevent unnecessary movement of the injured backbone.

Fractures and dislocations

Wilderness care for fractures recommends **immobilization** by using splints and slings. If manufactured splints and slings are not available in the medicine kit, they can be improvised by using natural materials, ski poles, ice axes, clothing, or parts of backpacks. In the case of **dislocations**, standard wilderness procedure is to splint, tape, and stabilize the injury in the current position. However, if circulation or nerve function is impaired, or if the injured person is in extreme pain, relocation may be necessary by realigning the injured area. Relocation is most effective if it is done immediately following the injury, before stiffness or **muscle spasms** set in.

Altitude sickness

Symptoms of **altitude sickness** include **headache**, nausea, **fatigue**, vomiting, and bluish skin. Ataxia, or loss of muscular control and balance indicates more severe altitude sickness. Altitude sickness can occur at altitudes above 8,000 feet. The best prevention of the condition is allowing plenty of time for acclimatization at high altitudes, drinking plenty of fluids, and eating a diet rich in carbohydrates. **Aspirin** or **acetaminophen** may be taken, while the drug acetazolamide (Diamox) can relieve symptoms of mild acute mountain sickness (AMS). Other related conditions, which can cause death, are high altitude cerebral **edema** (HACE), which causes fluid accumulation on the brain, and high altitude **pulmonary edema** (HAPE), which causes fluid in the lungs. The main treatment for acute mountain sickness is to rapidly descend to lower altitudes. In some cases oxygen may be available to ease symptoms.

Problems from cold and heat

Frostbite is localized tissue damage from exposure to cold and is remedied by the slow warming of exposed parts, preferably in heated water. Hypothermia is the condition resulting from lowered body core temperature and is a common affliction in wilderness medicine. Mild hypothermia occurs when the body's core temperature (measured rectally) falls from normal to 95°F (35°C) Fahrenheit. Moderate hypothermia gives temperatures between 90–95F (32.2-35°C), while severe hypothermia occurs when a body's core temperature falls below 90°F (32.2°C). Symptoms include severe shivering, confusion, apathy, drowsiness, slurred speech, and impaired reflexes and progresses to the point of unconsciousness.

Even cases of the mildest hypothermia must be cared for closely. Patients in whom hypothermia is suspected should be immediately warmed by gently removing wet clothing and providing dry clothing, blankets, and shelter. They should be monitored for body temperature changes. Severe hypothermia cannot

WWW.BOOKBAZ.IR

be remedied in the wilderness; victims must be immediately and gently evacuated. Warming severe hypothermia victims too quickly is dangerous. Cardiopulmonary resuscitation (CPR) may be initiated on victims of severe hypothermia who have cardiac arrest. In cases of near drowning, hypothermia must always be suspected.

Illness from heat includes heat exhaustion and the more severe heat **stroke**. Symptoms include confusion, rapid weak pulse, cramps, dizziness, nausea, diarrhea, headache, and high measured temperatures. Sweating may or may not occur, and the skin may be clammy and blotched. The principle treatment for heat illness in the wilderness is immediate cooling of the patient, by providing shade, fanning, sponging, and immersion in cold water. Heat exhaustion will correct itself with enough rest and water. Heat stroke is life threatening and requires immediate cooling and rehydration with fluids, preferably intravenous ones. Prevention of heat illness includes proper conditioning, protective clothing, and avoiding **dehydration**.

Insect, reptile, and animal bites

Wilderness medicine must deal with an array of **bites and stings**, from bears, snakes, reptiles, spiders, scorpions, bees, fish, and ticks. Prevention includes knowledge of the threats in the region being explored, as well as packing appropriate supplies such as bee sting kits for anaphylactic shock and snakebite kits for venomous attacks. The goal of treatment is to stop bleeding, prevent infection, and alleviate envenomation, or exposure to poison. The Sawyer Extractor is a suction tool used to remove snake venom, and the Epipen and Ana-kit are available by prescription for anaphylactic shock due to stings and severe allergic reactions.

Preparation

Knowledge and sound planning can be the difference between success and disaster in the backcountry. Members of extended wilderness outings should undergo thorough examinations by their physicians and dentists prior to undertaking expeditions. People going on wilderness outings should begin in a state of sound physical fitness by undertaking appropriate conditioning programs, as well as becoming acclimatized to special conditions such as altitude or extreme temperatures. Those with medications should be aware of potential side effects and complications, and inform other members of their group. At least two, and preferably all, members of wilderness expeditions should be familiar with first aid, wilderness medicine and rescue procedures. All members of wilderness outings should carry appropriate clothing, equipment, food, water, and first aid supplies. Trip itineraries should be recorded with park rangers or other official services. Means of communication with rescue facilities should be considered in advance in case emergencies arise.

KEY TERMS

Anaphylactic shock—Severe allergic reaction characterized by airway constriction, tissue swelling, and lowered blood pressure.

Cardiac arrest—Heart failure or heart attack.

Dislocation—Displacement of bones at a joint.

Envenomation—Exposure to venom by bites or stings from insects, reptiles, and fish.

Wilderness—Large backcountry areas lacking roads, communication and other modern infrastructure.

Carrying adequate medical supplies is a crucial preparation for wilderness outings. These supplies will vary depending on the length of the trip and the region. Medical kits should contain basic first aid supplies, such as bandages, dressings, pain relievers, water purification tablets, sunscreen, **antiseptics**, and ointments. Additional medical supplies include **antibiotics**, medications for gastrointestinal problems, **antihistamines**, and emergency kits for **asthma** or allergic reactions, snake and insect bite kits, splints, and basic surgical supplies. Extended expeditions or those facing extreme conditions might include intravenous fluids, oxygen bottles for altitude problems, rescue gear and evacuation equipment, and specific medications for regional diseases and infections, such as **malaria**.

Immunizations are a very important preparation for those entering wilderness areas, particularly in Third World countries. Immunizations should be planned as far in advance as possible, as some take several weeks to become effective and others cannot be given together. Some immunizations that may be required, depending on the region, include **tetanus**, poliovirus, **measles**, **mumps**, **rubella**, **cholera**, **yellow fever**, meningococcus, hepatitis, bubonic **plague**, **typhoid fever**, and **rabies**.

Several organizations provide training and certification for various levels of wilderness medicine. The most basic levels of preparation are first aid and first

responder certifications, followed by outdoor emergency care (OEC) training. More rigorous training provides the wilderness first responder (WFR), the wilderness emergency medical technician (WEMC), or the wilderness prehospital emergency care (WPHEC) certifications. The most advanced level of wilderness medical certification is search and rescue (SAR) emergency care, which provides expertise in a sophisticated array of rescue techniques and equipment.

Wilms' tumor

Definition

Wilms' tumor is a cancerous tumor of the kidney that usually occurs in young children. This tumor type is named for the German surgeon Max Wilms (1867–1918) and is also known as a nephroblastoma.

Demographics

Wilms' tumor occurs almost exclusively in young children. The average patient is about three years old, although cases have been reported in infants younger than six months and in adults in their early twenties. It is uncommon for this type of cancer to be diagnosed after age six years. Incidence of Wilms' tumor is slightly higher among African Americans and females. In the United States, about 500 new cases are diagnosed annually—the incidence rate has been stable for many years. Wilms' accounts for about 5% of all cancers diagnosed in children in the United States, and it is the most common type of renal cancer in children.

Description

When an unborn baby is developing, the kidneys are formed from primitive cells. Over time, these cells become more specialized. The cells mature and organize into normal kidney structure. Sometimes, clumps of these cells remain in their original, primitive form. If these cells begin to multiply after birth, they may ultimately form a large mass of abnormal cells. This is known as a Wilms' tumor.

Wilms' tumor is a type of malignant tumor, which means that it is made up of cells that are significantly immature and abnormal. These cells are also capable of invading nearby structures within the kidney and traveling out of the kidney into other structures. Malignant cells can even travel through the body to invade other organ systems, most commonly the lungs and brain. These features of Wilms' tumor make it a type of cancer that, without treatment, eventually causes death. However, advances in medicine during the last 20 years have made Wilms' tumor a very treatable form of cancer.

There are three types or variants of Wilms' tumors: those cases that develop sporadically; tumors that develop as part of genetic syndromes; and those that are familial or hereditary in nature. Most Wilms' tumors develop independent of genetic syndromes or family history although familial Wilms' tumor can be very common in some families.

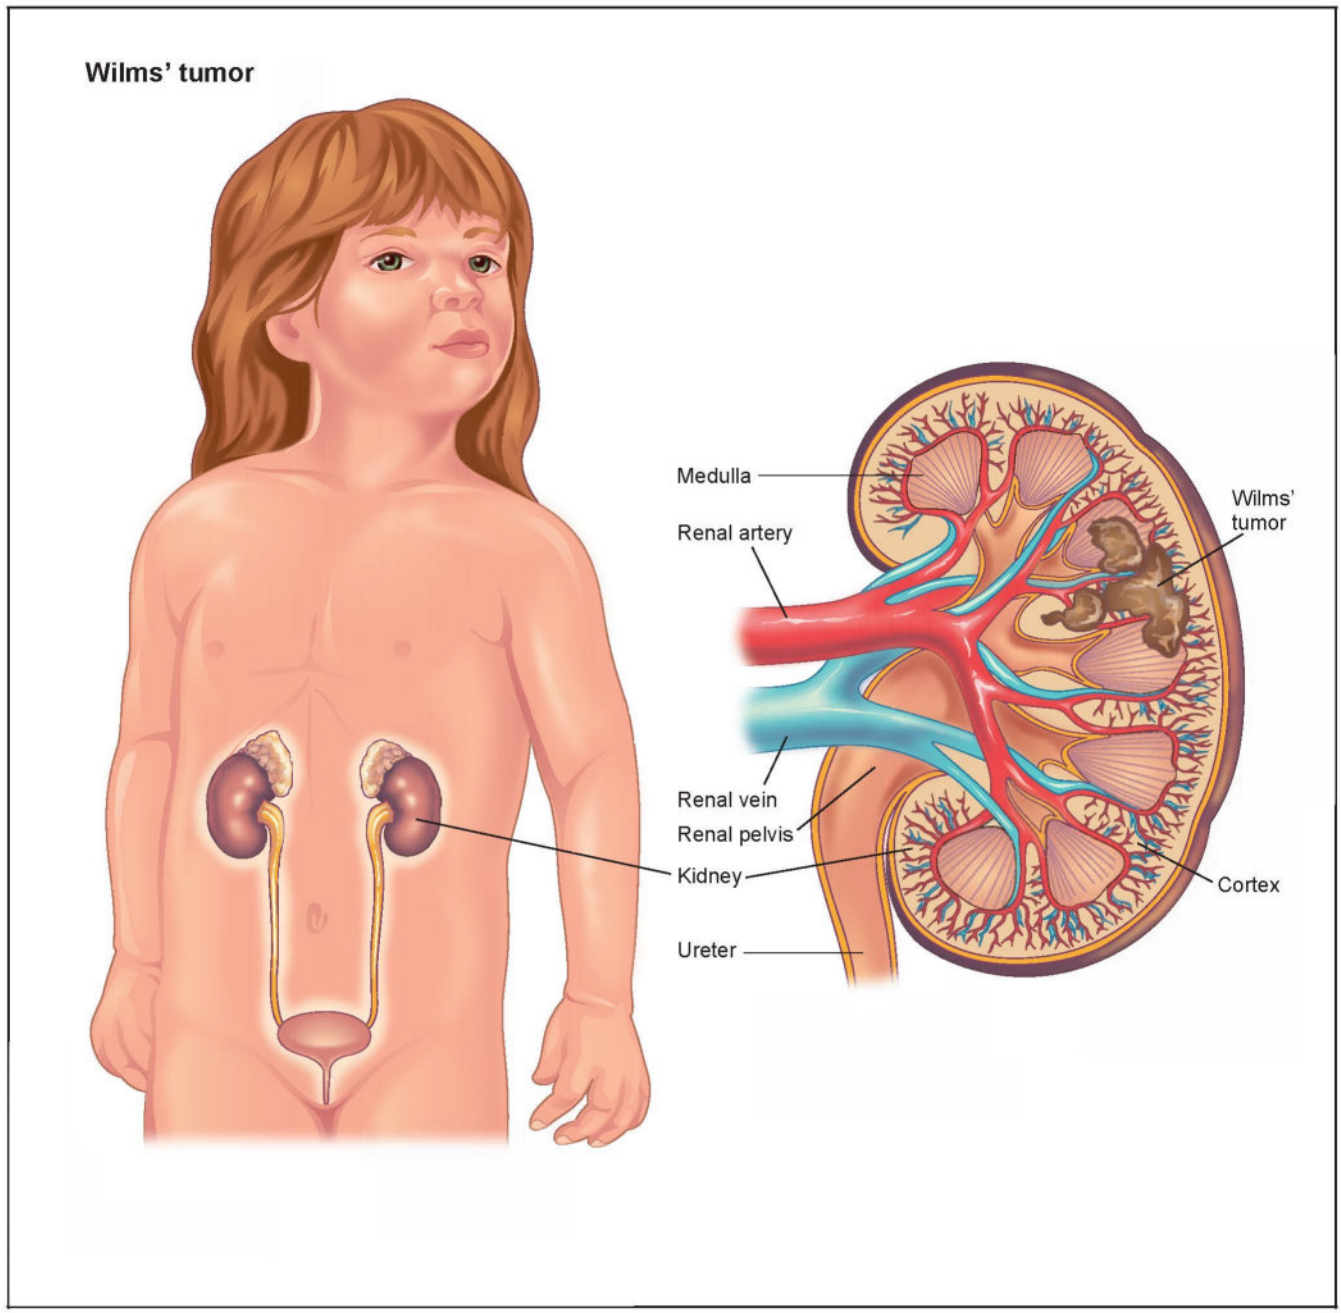
Wilms' tumors may be found in patients with other types of **birth defects**. These defects include:

- absence of the colored part (the iris) of the eye (aniridia)
- enlargement of one arm, one leg, or half of the face (hemihypertrophy)
- certain birth defects of the urinary system or genitals
- certain genetic syndromes (WAGR syndrome, Denys–Drash syndrome, and Beckwith–Wiedemann syndrome)

Causes and symptoms

The cause of Wilms' tumor is not completely understood. Because 15% of all patients with this type of tumor have other heritable defects, it seems clear that at least some cases of Wilms' tumor are due to an inherited alteration. A genetic defect known as WT1, the Wilms' tumor suppressor gene, has been identified in some patients on chromosome 11p13. It appears that the tendency to develop a Wilms' tumor can run in families. In fact, about 1.5% of all children with a Wilms' tumor have family members who have also had a Wilms' tumor. The genetic mechanisms

WWW.BOOKBAZ.IR



Wilms' tumor. *(Illustration by Electronic Illustrators Group. © Cengage Learning®.)*

associated with the disease are unusually complex. Researchers believe that the tumor develops because the defective WT1 gene fails to stop its growth.

Some patients with Wilms' tumor experience abdominal **pain**, nausea, **vomiting**, high blood pressure, or blood in the urine. However, the parents of many children with this type of tumor are the first to notice a firm, rounded mass in their child's abdomen. This discovery is often made while bathing or dressing the child and frequently occurs before any other symptoms appear. Rarely, a Wilms' tumor is diagnosed after there has been bleeding into the tumor, resulting in sudden swelling of the abdomen and a low red blood cell count (anemia).

About 4–5% of Wilms' tumor cases involve both kidneys during the initial evaluation. The tumor appears on either side equally. When pathologists look at these tumor cells under the microscope, they

KEY TERMS

Biopsy—A procedure in which a small sample of tissue is removed, prepared, and examined with a microscope to determine the characteristics of the tissue's cells.

Blastemal—An immature material from which cells and tissues develop.

Cancer—A process in which abnormal cells within the body begin to grow out of control, acquire the ability to invade nearby structures, and travel through the bloodstream and invade distant structures.

Malignant—Refers to cancer or cancer cells.

Sarcoma—A type of cancer that originates from connective tissue such as bone or muscle.

Stromal—A type of tissue that is associated with the support of an organ.

Tubule—Tissues and cells associated with the structures that connect the renal pelvis to the glomeruli.

see great diversity in the types of cells. Some types of cells are associated with a more favorable outcome in the patient than others. In about 15% of cases, physicians find some degree of cancer spread (metastasis). The most common sites in the body where metastasis occurs are the liver and lungs.

Researchers have found evidence that certain types of lesions occur before the development of the Wilms' tumor. These lesions usually appear in the form of stromal, tubule, or blastemal cells.

Diagnosis

When they first see a doctor, children with Wilms' tumor generally have a swollen abdomen or with an obvious abdominal mass. The physician may also find that the child has **fever**, bloody urine, or abdominal pain. The physician will order a variety of tests before imaging is performed. These tests mostly involve blood analysis in the form of a **white blood cell count**, **complete blood count**, coagulation profile, **platelet count**, and serum **calcium** evaluation. Liver and kidney function testing will also be performed, as well as a **urinalysis**. Other tests which may be ordered include testing for chromosome analysis and gene mapping.

Initial diagnosis of Wilms' tumor is made by looking at the tumor using various imaging techniques. **Ultrasound**, **computed tomography scans** (CT scans), and **magnetic resonance imaging** (MRI) are helpful in diagnosing Wilms' tumor. Final diagnosis, however, depends on obtaining a tissue sample from the mass (biopsy) and examining it under a microscope in order to verify that it has the characteristics of a Wilms' tumor. This biopsy is usually done during surgery to remove or decrease the size of the tumor. Other studies (chest x rays, CT scan of the lungs, bone scans) may also be done in order to see if the tumor has spread to other locations.

Treatment

In the United States, treatment for Wilms' tumor almost always begins with surgery to remove or decrease the size of the kidney tumor. Except in patients who have tumors in both kidneys, this surgery usually requires complete removal of the affected kidney. During surgery, the surrounding lymph nodes, the area around the kidneys, and the entire abdomen will also be examined. While the tumor can spread to these surrounding areas, it is less likely to do so as compared to other types of cancer. In cases where the tumor affects both kidneys, surgeons try to preserve the kidney with the smaller tumor by removing only a portion of the kidney, if possible. Additional biopsies of these areas may be done to see if the cancer has spread. The next treatment steps depend on whether and where the cancer has spread. Samples of the tumor are also examined under a microscope to determine particular characteristics of the cells making up the tumor.

Information about the tumor cell type and the spread of the tumor is used to decide the best kind of treatment for a particular patient. Treatment is usually a combination of surgery, medications used to kill cancer cells (**chemotherapy**), and x rays or other high–energy rays used to kill cancer cells (**radiation therapy**). These therapies are called adjuvant therapies, and this type of combination therapy has been shown to substantially improve outcome in patients with Wilms' tumor. It has long been known that Wilms' tumors respond to radiation therapy. Likewise, some types of chemotherapy have been found to be effective in treating Wilms' tumor. The most effective drugs include dactinomycin, doxorubicin, and vincristine. Cyclophosphamide can be added to the treatment regimen if the tumor is comprised of an unfavorable tumor type or if the cancer is in an advanced stage. The chemotherapy drugs cyclophosphamide, ifosfamide, cisplatin, carboplatin, and etoposide can be used to treat patients once they have relapsed following initial treatment. Chemotherapy may be administered preoperatively to some patients,

WWW.BOOKBAZ.IR

specifically for patients with tumor in both kidneys and to treat large tumors that are considered to be inoperable initially.

The National Wilms' Tumor Study Group (NWTSG) developed a staging system to describe Wilms' tumors. All of the stages assume that surgical removal of the tumor has occurred. Stage I involves "favorable" Wilms' tumor cells and is usually treated successfully with combination chemotherapy involving dactinomycin and vincristine for 18 weeks and without abdominal radiation therapy. Stage II tumors involving a favorable histology (cell characteristics) are usually treated with the same therapy as Stage I with the addition of the chemotherapy drug doxorubicin and are treated for 24 weeks. Stage III tumors with favorable histology are usually treated with combination chemotherapy consisting of doxorubicin, dactinomycin, and vincristine for 24 weeks, along with radiation therapy to the abdomen. Stage IV disease with a favorable histology is generally treated with combination chemotherapy with dactinomycin, doxorubicin, and vincristine. These patients usually receive abdominal radiation therapy and lung radiation therapy if the tumor has spread to the lungs. Patients in Stage IV with a favorable histology will also receive prophylactic administration of the antibiotic drug sulfamethoxazole and trimethoprim (Bactrim) to prevent infection with Pneumocystis carinii.

In the case of Stage II through IV tumors with unfavorable, or anaplastic, cells, then the previously mentioned combination chemotherapy is used along with the drug cyclophosphamide for 24 months. These patients also receive lung radiation therapy if the tumor has spread to the lungs as well as radiation to the abdomen. Another type of tumor cell can be present in Stages I through IV. This cell type is called clear cell sarcoma of the kidney. If this type of cell is present, then patients receive combination therapy with vincristine, doxorubicin, and dactinomycin. All of these patients receive abdominal radiation therapy and lung radiation therapy if the tumor has spread to the lungs.

Prognosis

The prognosis for patients with Wilms' tumor is quite good compared to the prognosis for most types of cancer. The overall survival rate has risen to approximately 90% during the past three decades. Patients who have the best prognosis are usually those who have a small-sized tumor, a favorable cell type, are young (especially under two years old), and have an early stage of cancer that has not spread. Modern treatments have been especially effective in the treatment of this cancer.

Genetic factors can be used to help determine the prognosis in some children diagnosed with Wilms' tumor. Children with genetic changes on chromosomes 1p and 16q, about 5% of children diagnosed with favorable-histology Wilms' tumor, appear to be at greater risk for relapse after initial treatment and are at greater risk of dying than children without these chromosomal changes.

Prevention

There are no known ways to prevent a Wilms' tumor, although it is important that children with birth defects associated with Wilms' tumor be carefully monitored. Some clinicians recommend screening using ultrasounds of the kidneys once or twice per year.

Copper deposits are visible as a ring around the iris in patients with Wilson disease. *(Photo Researchers, Inc.)*

Wilson disease

Definition

Wilson disease, or WD, is a rare inherited disorder that causes excess copper to accumulate in the body. It is also known as hepatolenticular degeneration. Steadily increasing amounts of copper circulating in the blood are deposited primarily in the brain, liver, kidneys, and the cornea of the eyes. WD is fatal if it is not recognized and treated. It is named for a U.S. neurologist, Samuel A. K. Wilson, who first described it in 1912.

Description

Under normal conditions, copper that finds its way into the body through the diet is processed within the liver. This processed form of copper is then passed into the gallbladder, along with the other components of bile (a fluid produced by the liver, which enters the small intestine in order to help in digestive processes). When the gallbladder empties its contents into the first part of the small intestine (duodenum), the copper in the bile enters and passes through the intestine with the waste products of digestion. In healthy individuals, copper is then passed out of the body in stool.

In Wilson disease, copper does not pass from the liver into the bile, but rather begins to accumulate within the liver. As copper levels rise in the liver, the damaged organ begins to allow copper to flow into the bloodstream, where it circulates. Copper is then deposited throughout the body, building up primarily in the kidneys, the brain and nervous system, and the eyes. Wilson disease, then, is a disorder of copper **poisoning** occurring from birth.

Wilson disease affects approximately 1 in 30,000 to 1 in 100,000 individuals and can affect people from many different populations. Approximately one in 90 individuals are carriers of the gene for Wilson disease.

Causes and symptoms

Wilson disease is inherited in an autosomal recessive manner. Autosomal recessive refers to the pattern of inheritance where both parents carry a gene for the disease on one of their chromosome pairs. When each parent passes on the chromosome with the gene for Wilson disease, the child will be affected with the disease. Both males and females can be affected with Wilson disease. If an individual is a carrier of the Wilson disease gene they do not have any symptoms of this disease. In order to be affected, an individual must inherit two copies of the gene, one from each parent. Many cases of Wilson disease may not be inherited but occur as a spontaneous mutation in the gene.

The gene for Wilson disease is located on chromosome number 13. The name of the gene is called ATP7B and is thought to be involved in transporting copper. More than 200 different mutations of this gene have been identified, making diagnosis by **genetic testing** difficult.

Symptoms typically present between the ages of 3 and 60, with age 17 considered to be the average age a diagnosis is made. About half of all patients experience their first symptoms in the liver. The illness causes swelling and tenderness of the liver, sometimes with **fever**, mimicking more common disorders, such as viral hepatitis and **infectious mononucleosis**. Abnormal levels of circulating liver enzymes reveal that the liver is being seriously damaged. This form of damage is referred to as fatty degeneration. Without medical intervention, the liver damage will progress to actual **cirrhosis**. An often-fatal manifestation of **liver disease** is called fulminant hepatitis. This extremely severe inflammation of the liver (hepatitis) results in **jaundice**, fluid leaking into the abdomen, low protein

WWW.BOOKBAZ.IR

circulating in the blood, abnormalities of the blood clotting system, swelling of the brain, and anemia due to the abnormal destruction of red blood cells.

Neurological symptoms are the first to occur in half of all patients due to copper accumulation in the brain and nervous system. The average age of onset for neurological symptoms is 21. These symptoms include **tremors** of the hands, uncontrollable movements of the limbs, stiffness, drooling, difficulty swallowing, difficulty talking, and **headache**. There is no change in patient's intelligence.

About one-third of all patients with Wilson disease have a variety of psychiatric symptoms as the first signs of the disease. These symptoms include inability to cope, depression, irritability, increased anger, and inappropriate behavior. Often times patients have trouble completing tasks at work or in school.

Other symptoms that can affect patients with Wilson disease, and may occur before or after a diagnosis has been made, include joint disorders, symptoms of arthritis, and skeletal problems such as **osteoporosis**. Patients have occasionally been affected with **kidney stones**, abnormal handling of glucose in their body, and women have menstrual cycle irregularities including stopping their regular cycle temporarily.

Diagnosis

The diagnosis of Wilson disease can be performed relatively easily through several different tests; however, because Wilson disease is so rare, diagnosis is often unfortunately delayed. The tests used to diagnose Wilson disease can be performed on patients who have and who have not already shown symptoms of the disease. It is extremely important to make a diagnosis as soon as possible since liver damage can occur before there are any signs of the disease.

An easy way to diagnose Wilson disease is to measure the amount of a glycoprotein found in the blood called ceruloplasmin. Low levels of ceruloplasmin can diagnose the disease in about 80% of affected patients. This procedure is not as effective for women taking birth control pills, pregnant women, or infants younger than six months of age.

A second test involving an **eye examination** to detect a characteristic ring of copper deposited in a membrane of the cornea (referred to as Kayser-Fleischer rings) is very easy to perform and is very useful in diagnosing patients who have already exhibited symptoms. This test is not as effective in persons without symptoms. This diagnostic test cannot be used by itself to make a diagnosis because some patients with liver disease but not Wilson disease will test positive.

A third test for diagnosing Wilson disease involves measuring the amount of copper in the liver. This can be accomplished by sampling a portion of the liver, called a biopsy. This is one of the most effective ways in which to diagnose Wilson disease, but the procedure itself is more difficult to perform than the others.

Other tests are also useful, for example measuring the amount of copper passed into the urine daily (high in Wilson disease). Another lab test measures the ability of a patient's ceruloplasmin to bind with a form of copper (decreased in Wilson disease). Finally, some patients can be diagnosed through a DNA test to determine whether or not they carry two genes for Wilson disease. This test does not always prove to be useful in certain patients and is of most use when used to test the brothers and sisters of affected patients.

Molecular genetic testing is not particularly valuable in diagnosing WD because of the large number of possible gene mutations.

Treatment

Treatment involves life-long administration of either D-penicillamine (Cuprimine, Depen) or trientine hydrochloride (Syprine). Both of these drugs remove copper deposits throughout the body by binding to the copper which then leaves the body in the urine. This type of treatment is called **chelation therapy**. Zinc acetate (Galzin) and a low copper diet are other ways in which to treat Wilson disease.

Penicillamine has a number of serious side effects:

- joint pain
- neurological problems
- systemic lupus erythematosus
- decreased production of all blood elements
- interference with clotting
- allergic reactions

Careful monitoring is necessary. When patients have side effects from penicillamine, the dose can sometimes be lowered to an effective level that causes fewer difficulties. Alternatively, steroid medications may be required to reduce certain sensitivity reactions. Trientine has fewer potential side effects, but must still be carefully monitored.

Treatment with zinc acetate is also an effective way to remove excess copper from the body. Zinc is a metal that works to block copper absorption and bind copper in the intestinal cells until it is all released into the stool approximately one week later. The benefit of treatment with zinc is there are no toxic side effects however the

KEY TERMS

Anemia—A blood condition in which the level of hemoglobin or the number of red blood cells falls below normal values. Common symptoms include paleness, fatigue, and shortness of breath.

Bile—A substance produced by the liver and concentrated and stored in the gallbladder. Bile contains a number of different substances, including bile salts, cholesterol, and bilirubin.

Biopsy—The surgical removal and microscopic examination of living tissue for diagnostic purposes.

Cell—The smallest living units of the body which group together to form tissues and help the body perform specific functions.

Ceruloplasmin—A protein circulating in the bloodstream that binds with copper and transports it.

Chelation therapy—A method of removing copper or other heavy metals from the body by giving medications that bind to the metal and allow it to be excreted.

Chromosome—A microscopic thread-like structure found within each cell of the body and consists of a complex of proteins and DNA. Humans have 46 chromosomes arranged into 23 pairs. Changes in either the total number of chromosomes or their shape and size (structure) may lead to physical or mental abnormalities.

Cirrhosis—A chronic degenerative disease of the liver, in which normal cells are replaced by fibrous tissue. Cirrhosis is a major risk factor for the later development of liver cancer.

Deoxyribonucleic acid (DNA)—The genetic material in cells that holds the inherited instructions for growth, development, and cellular functioning.

Gallbladder—A small, pear-shaped organ in the upper right hand corner of the abdomen. It is connected by a series of ducts (tube-like channels) to the liver pancreas, and duodenum (first part of the small intestine). The gallbladder receives bile from the liver and concentrates and stores it. After a meal, bile is squeezed out of the gallbladder into the intestine, where it aids in digestion of food.

Gene—A building block of inheritance, which contains the instructions for the production of a particular protein, and is made up of a molecular sequence found on a section of DNA. Each gene is found on a precise location on a chromosome.

Glucose—One of the two simple sugars, together with galactose, that makes up the protein, lactose, found in milk. Glucose is the form of sugar that is usable by the body to generate energy.

Hepatitis—A viral disease characterized by inflammation of the liver cells (hepatocytes). People infected with hepatitis B or hepatitis C virus are at an increased risk for developing liver cancer.

Jaundice—Yellowing of the skin or eyes due to excess of bilirubin in the blood.

Toxic—Poisoinous.

zinc is a slower acting agent than the other drugs. It takes four to eight months for the zinc to be effective in reducing the overall amount of copper in the body.

Finally, patients with Wilson disease are encouraged to follow a diet low in copper, with an average copper intake of 1.0 mg per day. Foods to be avoided for the high levels of copper include liver and shellfish. Patients are also instructed to monitor their drinking water for excess levels of copper and drink distilled water instead.

Patients may be given a liver transplant in the event of liver failure as a complication of WD. **Liver transplantation** has been reported to have a relatively favorable outcome, in some cases decreasing the patient's neurologic symptoms.

Prognosis

Without treatment, Wilson disease is always fatal. With treatment, symptoms may continue to worsen for the first six to eight weeks. After this time, definite improvement should begin to be seen. However, it may take several years (two to five) of treatment to reach maximal benefit to the brain and liver. Even then, many patients are not returned to their original level of functioning. Patients with Wilson disease need to maintain some sort of anticopper treatment for the rest of their lives in order to prevent copper levels from rising in the body. Interruptions in treatment can result in a relapse of the disease which is not reversible, and can ultimately lead to death.

Wiskott-Aldrich syndrome

Definition

Wiskott-Aldrich syndrome (WAS) is a rare inherited disorder **immunodeficiency** disorder marked by a low level of blood platelets (**thrombocytopenia**), **eczema**, recurrent infections, and a high risk of leukemia or lymph node tumors.

Demographics

WAS syndrome is rare. It affects about 1 in every 250,000 male children and occurs worldwide. Children are born with the genetic defect that causes this syndrome and usually do not live beyond childhood.

Description

WAS is named for the two physicians who first reported the disorder. In 1937, Dr. A. Wiskott, a physician working in Munich, Germany, described two affected boys of German ancestry who had repeated infections, a skin rash, and poor blood-clotting ability. Nearly 20 years later, Dr. R. A. Aldrich reported similar symptoms in members of a U.S. family of Dutch ancestry.

WAS is inherited as a rare X-linked genetic disorder and therefore affects only males. The gene responsible for WAS, officially called the Wiskott-Aldrich syndrome (eczema-thrombocytopenia) gene or WAS gene, is located on the short arm of the X chromosome. Since males have only one X chromosome, they have only one copy of the genes on this chromosome. If their copy of the WAS gene is abnormal, they will have WAS. In contrast, females have two X chromosomes. They can have a normal copy of the WAS gene on one chromosome, even if they have an abnormal WAS gene on the other. Because the defective gene that causes WAS is rare and usually causes death in childhood, it is highly unlikely that a female will have two defective copies of the gene. The single normal copy of the WAS gene on one X chromosome is sufficient to prevent females from having WAS. However, women who have one abnormal copy of the WAS gene are designated as carriers. While they will not have WAS, they have a 50% chance of passing the gene to each of their sons who will have WAS. Carrier females also have a 50% risk of passing the defective copy of the gene to their daughters who also become carriers.

Researchers identified the gene for WAS in 1994 and pinpointed its location on the short arm of the X chromosome. As of 2015, over 350 different mutations have been found in the gene among WAS patients. The fact that there are many mutations may explain some of the variability of symptoms among boys with WAS. However, even within the same family, affected individuals with the identical WAS gene mutation may have different degrees of severity of the disease. The mild form, called X–linked thrombocytopenia, is also caused by mutations in this same gene.

Causes and symptoms

The syndrome is caused by a defect (mutation) in a specific gene called the WAS gene that normally codes for the protein named Wiskott-Aldrich Syndrome Protein (WASP). This vital protein is a component of cells that are important in the body's defense against infection (lymphocytes). The same protein also functions in cells that help prevent bleeding (platelets). A less severe form of the disease, X–linked thrombocytopenia, affects mainly platelets.

Increased susceptibility to infections, eczema, and excessive bleeding are hallmarks of WAS, although symptoms can vary significantly from one patient to

KEY TERMS

Amniocentesis—A procedure performed at 16–18 weeks of pregnancy in which a needle is inserted through a woman's abdomen into her uterus to draw out a small sample of the amniotic fluid from around the baby. Either the fluid itself or cells from the fluid can be used for a variety of tests to obtain information about genetic disorders and other medical conditions in the fetus.

Anemia—A blood condition in which the level of hemoglobin or the number of red blood cells falls below normal values. Common symptoms include paleness, fatigue, and shortness of breath.

B cells (B lymphocytes)—A type of white blood cell that produces antibodies.

Chorionic villus biopsy—A procedure used for prenatal diagnosis at 10–12 weeks gestation. Under ultrasound guidance a needle is inserted either through the mother's vagina or abdominal wall and a sample of cells is collected from around the early embryo. These cells are then tested for chromosome abnormalities or other genetic diseases.

Eczema—Inflammation of the skin with redness and other variable signs such as crusts, watery discharge, and itching.

Gene—A building block of inheritance which contains the instructions for the production of a particular protein and is made up of a molecular sequence found on a section of DNA. Each gene is found on a precise location on a chromosome.

Immune system—The mechanism that protects the body from foreign substances, foreign cells, and pathogens. The thymus, spleen, lymph nodes, white blood cells, including the B cells and T cells, and antibodies are involved in the immune response, which aims to destroy these foreign bodies.

Mutation—A permanent change in the genetic material that may alter a trait or characteristic of an individual, or manifest as disease, and can be transmitted to offspring.

Platelets—Small disc–shaped structures that circulate in the blood stream and participate in blood clotting.

Prenatal diagnosis—The determination of whether a fetus possesses a disease or disorder while it is still in the womb.

Syndrome—A group of signs and symptoms that collectively characterize a disease or disorder.

T cells (T lymphocytes)—White blood cells that originate in the thymus gland. T cells regulate the immune system's response to infections, including HIV. CD4 lymphocytes are a subset of T lymphocytes.

Thrombocytopenia—A persistent decrease in the number of blood platelets usually associated with hemorrhaging.

X–linked—Located on the X chromosome, one of the sex chromosomes. X–linked genes follow a characteristic pattern of inheritance from one generation to the next.

another. The immune system of patients with WAS produces too few B and T cells. B cells are cells in the body that make antibodies. There are many types of T cells. Both B and T cells are needed to defend the body against infection. Because both types of cells are affected, WAS patients are subject to repeated infections from bacteria, fungi, and viruses. Ear infections, **meningitis**, and **pneumonia** are common in boys with WAS.

WAS patients also have thrombocytopenia, a decreased number of platelets. Platelets are specialized blood cells that help to form **blood clots** and prevent uncontrolled bleeding. The platelets also may be smaller than normal. Some of the earliest symptoms of the syndrome are hemorrhage from **circumcision**, bloody **diarrhea**, and a tendency to bruise very easily.

Anemia and an enlarged spleen (splenomegaly) are seen in some patients. About 10% of patients develop malignancies (cancers), usually leukemia or tumors in the lymph nodes (non-Hodgkin's lymphoma).

Diagnosis

The diagnosis of WAS is usually suspected in male infants who have excessive bleeding, eczema, and frequent bacterial or viral infections. Special blood tests can then be ordered to confirm WAS. The blood of Wiskott-Aldrich patients will show a low **platelet count** and a weak immune (antibody) response. It is also possible to confirm the diagnosis by obtaining a small sample of the patient's blood and analyzing the DNA for a mutation in the WAS gene. Knowledge of the exact mutation combined with information about how much WAS protein the defective gene can produce may help predict how severe a form of the disease an individual will have.

WWW.BOOKBAZ.IR

Carrier Testing

If the specific WAS gene mutation is identified in an affected child, that child's mother can then be tested to confirm that she carries the gene. Other members of the mother's family may also want to consider testing to find out if they carry the same gene mutation. The first step in studying other family members is for a geneticist or genetic counselor to obtain a detailed family history and construct a pedigree (family tree) to determine which family members should be offered testing.

Prenatal Diagnosis

In families where one child has been born with WAS, prenatal testing should be offered in subsequent pregnancies. There is a 50% chance with each subsequent **pregnancy** that the mother, who is a carrier, will transmit the abnormal copy of the gene to her baby. The key is to first identify the particular WAS gene mutation in the child with WAS. Then, early in a pregnancy, cells can be obtained from the developing fetus by **chorionic villus sampling** or **amniocentesis**, and checked for the same mutation. Women who carry the abnormal WAS gene and are considering prenatal diagnosis should discuss the risks and benefits of this type of testing with a geneticist or genetic counselor.

Treatment

Standard treatments for individuals with WAS include **antibiotics** for infections and platelet transfusions to limit bleeding. Immune globulin is given to strengthen the individual's immune system. Eczema can be treated with corticosteroid creams applied directly to the skin. The spleen is sometimes removed to reduce the risk of bleeding. In individuals with WAS, however, removal of the spleen also increases the risk of infection unless antibiotics are given to prevent infections.

About 50% of individuals with WAS are helped by treatment with transfer factor, which is a substance derived from the T cells of a healthy person. Transfer factor is given to improve both blood clotting and immune functions. **Bone marrow transplantation** has been successful in a number of cases. It has been most successful in boys under five years of age where the donor is a sibling whose tissue type closely matches that of the individual with WAS. Bone marrow transplantation can cure this condition but a highly matched donor must be found, transplantation should occur before age five, and the procedure carries substantial risks. Investigation into treatment with **gene therapy** was ongoing as of 2015.

Prognosis

Prognosis for males diagnosed with Wiskott-Aldrich syndrome who do not undergo successful bone marrow transplantation is poor. The average individual lives about six years; those who survive into adolescence often develop cancer. Death usually occurs from severe bleeding or overwhelming infection in the first few years of life.

Prevention

Wiskott-Aldrich syndrome is a genetic defect present at birth and cannot be prevented.

Withdrawal syndromes

Definition

Withdrawal syndrome occurs in drug and alcohol addicted individuals who discontinue or reduce the use of their drug of choice. This process of eliminating

drugs and alcohol from the body is known as **detoxification**. **Anxiety**, **insomnia**, nausea, perspiration, body aches, and **tremors** are just a few of the physical and psychological symptoms of drug and alcohol withdrawal that may occur during detoxification.

Description

Drugs and alcohol affect mood by altering brain chemistry, specifically the production of neurotransmitters. Neurotransmitters are chemicals in the central nervous system that enable nerve impulses to travel through the central nervous system and regulate thought processes, behavior, and emotion. Drugs that temporarily elevate neurotransmitter levels are called stimulants. Drugs that decrease neurotransmitter levels and depress the central nervous system are called depressants; they include opiates and sedative-hypnotic drugs such as alcohol and **barbiturates**. (There are exceptions: benzodiazepine elevates the level of an inhibitory neurotransmitter, GABA, therefore it serves as a tranquilizer.)

When drug or alcohol consumption becomes chronic, the body adjusts to the constant presence of the substance by changing its normal production of neurotransmitters. If drug and alcohol use suddenly stops, the body and central nervous system react to the absence of the substance with an array of symptoms known collectively as withdrawal syndrome.

Causes and symptoms

Acute withdrawal syndrome begins within hours of abstinence and includes a full range of physical and psychological symptoms. More long-term, or subacute, withdrawal symptoms, such as intense drug craving, may occur weeks or months after detoxification has taken place.

Alcohol withdrawal

Alcohol withdrawal syndrome occurs in alcohol-dependent individuals who suddenly stop or dramatically reduce their alcohol intake. The onset of the syndrome is likely to occur within a week, but usually occurs within 24 hours of the individual's last drink and is triggered when the central nervous system attempts to adjust to the sudden absence of ethyl alcohol in the body. Symptoms may include extreme anxiety, disorientation, **hallucinations**, **sleep disorders**, hand tremors, nausea, sweating, seizures, and racing pulse. **Delirium** tremens (DTs) are an extreme example of withdrawal. In the worst cases, untreated alcohol withdrawal syndrome can result in death. As many as two million Americans may experience symptoms of alcohol withdrawal conditions each year.

Barbiturate withdrawal

Barbiturates are prescribed as anticonvulsants, sedatives, and general anesthetics. They can also mimic some of the characteristics of alcohol intoxication (including euphoria, elation, and uninhibited behavior), which make them candidates for abuse. Commonly abused barbiturates include amobarbital (Amytal), pentobarbital (Nembutal), and secobarbital (Seconal). These drugs depress the respiratory and nervous system functions. Because abusers rapidly build up a tolerance to the effects of the drug, fatal overdose or **coma** can easily occur. Symptoms of withdrawal syndrome appear 12-20 hours after the last dose; they include anxiety, irritability, elevated heart and respiration rate, muscle **pain**, nausea, tremors, hallucinations, confusion, and seizures. Death is a possibility if the condition is left untreated. Because barbiturates decrease REM (rapid eye movement) sleep, during which dreaming takes place, withdrawal often results in sleep disruptions such as nightmares, insomnia, or vivid dreaming.

Opiate withdrawal

Opiates are powerfully addictive analgesic drugs that deaden nerve pathways related to pain. Abusers of propoxyphene (Darvon), meperidine (Demerol), percocet (Oxycodone), heroin, morphine, and other powerfully addictive opiates quickly build up a tolerance to the drugs and need progressively larger doses to achieve the desired effect. Stopping or reducing the intake of the drug can cause severe withdrawal symptoms, which begin six to eight hours after the last dosage. Symptoms are flu-like and include gastrointestinal distress, anxiety, nausea, insomnia, muscle pain, fevers, sweating, and runny nose and eyes.

Stimulant withdrawal

Use of stimulants, such as cocaine, crack, amphetamines, and methamphetamines, cause an increase in neurotransmitters in the central nervous system and produce feelings of alertness and increased energy. This initial "rush" is followed by a longer period of neurotransmitter loss, characterized by depression, lethargy, and a craving for more stimulants sometimes called a rebound effect. When a stimulant-dependent individual abstains from stimulant use, withdrawal symptoms, including depression, **fatigue**, insomnia, and loss of appetite, reflect this drop in neurotransmitter levels. Withdrawal typically takes one to two weeks.

WWW.BOOKBAZ.IR

Diagnosis

A detailed history of the patient's drug or alcohol use taken before detoxification can be helpful in predicting the severity of withdrawal symptoms. Standardized clinical tests, such as the Clinical Institute Withdrawal Assessment for Alcohol, revised, (CIWA-Ar), are used to evaluate the severity of withdrawal symptoms throughout the detoxification procedure.

Treatment

Pharmacologic and medical management is often recommended for withdrawal syndrome. The physical condition of the patient is closely monitored throughout the detoxification procedure.

Alcohol withdrawal

Alcohol withdrawal syndrome can be treated at home or in a hospital or treatment setting. Inpatient treatment is recommended for patients who are at risk for serious withdrawal symptoms or re-intoxication if treated as an outpatient. Withdrawal symptoms are minimized through the administration of cross-tolerant sedatives. Long-acting **benzodiazepines**, such as diazepam (Valium), chlordiazepoxide (Librium), and lorazepam (Ativan), are the pharmacologic treatments of choice in managing the symptoms of alcohol withdrawal. Drug dosage is adjusted to offset the discomfort of withdrawal, without causing a euphoric effect, and is then gradually decreased as withdrawal symptoms lessen.

Barbiturate withdrawal

Because the risk for seizures and other severe complications is high, barbiturate withdrawal should be monitored in a hospital setting. Patients are given low doses of phenobarbital at a regular interval until mild intoxication is achieved. The dosage amount and frequency is then gradually decreased until withdrawal is complete.

Opiate withdrawal

Two basic treatment approaches are used for managing opiate withdrawal. The first involves treating the symptoms of the withdrawal with appropriate medication. Clondine, an antihypertensive drug, is commonly prescribed to reduce muscle pain and cramping. Other symptom-specific drugs are administered on an as-needed basis.

The second treatment option is to replace the patient's drug of choice with **methadone**, a long-acting, cross-tolerant opiate that does not normally produce a "high." Doses of methadone are administered every four to six hours. The patient's reaction is closely observed, and dosages are slowly decreased until withdrawal symptoms have disappeared, then dosages are discontinued. Methadone withdrawal can be completed within three weeks. It is important to note that methadone withdrawal treatment differs from a methadone maintenance program, in which patients who are unwilling to give up opiates are prescribed methadone as a legal, long-term substitute for their drug of choice.

Rapid opiate detoxification (ROD) is an emerging treatment option for opiate withdrawal. The ROD method is reported to be faster and to cause less physical discomfort than traditional forms of opiate detoxification. The treatment is typically performed in a hospital or private clinic setting. Naltrexone, an opiate antagonist that blocks opiate receptors and reverses the effects of opiates, is administered to trigger the withdrawal response. Clonidine is given simultaneously to ease the symptoms of withdrawal. The patient is anesthetized throughout the three to four hour procedure, and withdrawal occurs while the patient sleeps. Vital signs are monitored closely and a ventilator may be employed.

KEY TERMS

Analgesics—Pain killing drugs that depress respiratory function. Opiates are analgesics.

Antagonist—A substance that tends to nullify the action of another.

Benzodiazepines—Sedatives used to treat anxiety, epilepsy, and alcohol withdrawal syndrome. Diazepam (Valium), alprazolam (Xanax), and chlordiazepoxide (Librium) are all benzodiazepines.

Cross-tolerant—A drug that has the same pharmacological effect as another is considered cross-tolerant. Cross-tolerant drugs are often used in treating withdrawal syndromes.

Detoxification—The process of physically eliminating drugs and/or alcohol from the system of a substance-dependent individual.

Dysphoria—A depressed and anxious mood state.

Neurotransmitters—Chemicals in the brain that affect the nervous system and alter thinking patterns.

Opiates—Analgesic, pain killing drugs, such as heroin and morphine that depress the central nervous system.

In early 2004, a new single injection method for opiate **addiction** was being tested. It consisted of a slow-release form of buprenorphine and prevented symptoms for an entire month.

Stimulant withdrawal

Because of the depression and dysphoria (feeling of a psychological low) related to stimulant withdrawal, psychological and/or medical management is critical. Treatment may include a regimen of drugs that increase neurotransmitter production.

Prognosis

A closely observed, medically managed detoxification typically results in a safe and tolerable withdrawal experience for the patient. Detoxification is only a short-term solution for obtaining abstinence. An addiction treatment and long-term recovery program is necessary to achieve long-term sobriety. Without such a treatment program, the likelihood of recurrence of abuse, and, therefore, the recurrence of withdrawal syndrome, is high.

Prevention

After detoxification, alcohol and drug dependent individuals are encouraged to maintain their abstinence through participation in substance abuse treatment or a 12-step recovery program.

Wolff-Parkinson-White syndrome

Definition

Wolff-Parkinson-White syndrome is an abnormality in the electrical functioning of the heart which may cause rapid heart rates. The abnormality affects the electrical signal between the atria and ventricles.

Description

Blood is circulated through the heart and body by a muscular pump and valve system involving the atria and ventricles. The right atrium receives oxygen-lacking blood returning to the heart from the body. The blood is passed from the right atrium into the right ventricle, which contracts and sends blood out to the pulmonary artery. The pulmonary artery sends the blood into the lungs, where carbon dioxide is removed, and fresh oxygen is added. The left atrium receives blood with oxygen from the lungs and passes this arterial blood to the left ventricle, where it is emptied into the aorta, the main artery of the heart.

These functions are directed by electrical signals within the heart. In patients afflicted with Wolff-Parkinson-White syndrome, an abnormal pathway exists that causes additional electrical signals to pass between the atria and ventricles, possibly causing rapid heart rate.

Causes and symptoms

Congenital heart disease may contribute to this and other **arrhythmias**. Ebstein's anomaly, a congenital heart defect that involves displacement of the tricuspid valve, located on the right side of the heart, is one known cause of Wolff-Parkinson-White syndrome. This anomaly allows blood to flow via the small hole to the other side of the heart. Often, there is no known cause for Wolff-Parkinson-White syndrome. Many people with the syndrome have no symptoms. However, some people experience temporary rapid heartbeat due to certain drugs, **smoking**, and **anxiety**.

Diagnosis

Electrocardiography (ECG) is used to diagnose Wolff-Parkinson-White syndrome and other cardiac arrhythmias. A trained physician, normally a cardiologist, can recognize patterns of electrical conduction. With this syndrome, the extra pathway will show a pattern different from those of normal conduction. If no irregular patterns show on the ECG, the patient

WWW.BOOKBAZ.IR

KEY TERMS

Ablative—Used to describe a procedure involving removal of a tissue or body part or destruction of its funtion.

Arrhythmia—Irregular heart beat.

Electrocardiograph (ECG)—A test of a patient's heartbeat that involves placing leads, or detectors, on the patient's chest to record electrical impulses in the heart. The test will produce a strip, or picture record of the heart's electrical function.

Tachycardia—Rapid heart rate, defined as more than 100 beats per minute.

may be sent home with a 24-hour heart monitor, called a Holter monitor, which will help detect intermittent occurrences. Other studies, such as the cardiac electrophysiologic study (EPS), may be ordered to pinpoint the location of the accessory pathway and to determine a course of treatment.

Treatment

Various drugs may be used to treat Wolff-Parkinson-White syndrome, as well as other cardiac arrhythmias. The purpose of these drugs is to slow the electrical signals and excitation of heart muscles. As some of these drugs may have side effects, including the rare production of new or more frequent arrhythmias, the patient should be carefully observed. Ablative therapies may be accomplished with radiofrequency or cardiac catheters to cut through the tissue which is causing the abnormal electrical signals.

At one time, only open heart surgery was used, but the procedure can be done now with local **anesthesia** in a special cardiac laboratory. In some cases, surgery may still be recommended to treat Wolff-Parkinson-White syndrome.Young people with this syndrome may be treated more successfully with surgery, rather than enduring a lifetime of drug treatments, or the possible threat of **sudden cardiac death**.

Alternatives

A provider may teach patients methods to help control heart rate. Relaxation techniques, **acupuncture**, botanical medicine, and homeopathy can all be helpful supportive therapies.

Prognosis

Most patients with this syndrome can lead normal lives, even with episodes of tachycardia. In many cases, the syndrome is secondary to the underlying congenital heart defect. However, Wolff-Parkinson-White syndrome can cause sudden cardiac arrest in certain instances.

Prevention

If the syndrome is not due to congenital **heart disease**, the patient may try avoiding behaviors which lead to arrhythmia, such as elimination of **caffeine**, alcohol, cocaine, and smoking.

Women's health

Definition

Women's health is concerned with how disease and health issues affect women and with diseases and conditions that affect women at higher rates throughout the life cycle. It promotes the inclusion of gender perspectives in a broad spectrum of health issues.

Statistics on women's health

Characteristic	Percentage of U.S. women	Age
In fair or poor health	14%	18+
Without health insurance	15%	<65
Currently smoke	16 %	18+
Engage in regular physical activity	45%	18+
Have hypertension	33%	20+
Are obese	36%	20+
Had a mammogram in the past 2 years	76%	40+
Had a Pap smear in the past 3 years	73%	18+

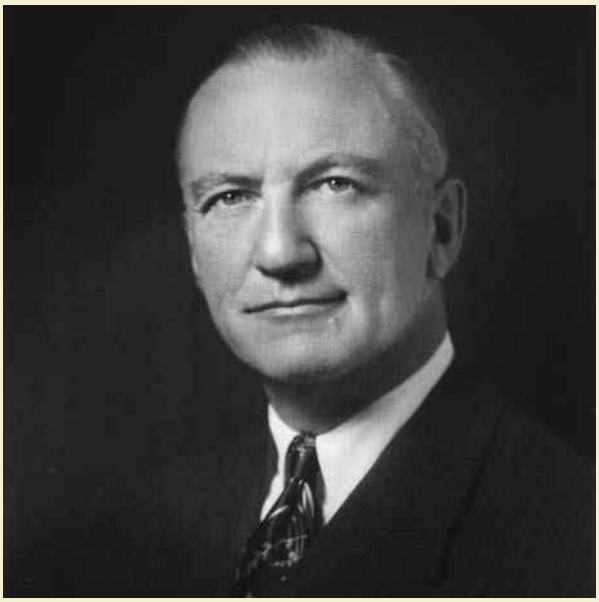
ARNOLD KEGEL (1894–1981)



Arnold Kegel. *(Images from the History of Medicine (NLM))*

American gynecologist Arnold Kegel (1894–1981) invented the exercises that bear his name. Kegel lived in the Los Angeles, California, area and was an assistant professor of gynecology at the University of Southern California's Keck School of Medicine. His work brought him into contact with many female patients who had problems with urinary stress incontinence and genital relaxation.

Urinary stress incontinence causes a sudden unintentional discharge of urine during periods of muscle activity, such as laughing, coughing, or sneezing. Genital relaxation is a weakening of the vaginal muscles, which can lead to uterine prolapse and other disorders. Both disorders commonly occur after childbirth and can also occur as a part of the aging process. Many women during the early part of the twentieth century endured the discomfort and embarrassment associated with these problems because the issues were generally believed not to be serious enough to warrant the risks of surgery, the only available treatment at that time.

While researching these two disorders, Kegel realized that the degeneration of a single muscle, the pubococcygeus, also known as the pelvic-floor muscle, could be responsible for both issues. The pubococcygeus stretches from the pubic bone to the coccyx (tailbone) and exists in both men and women, although Kegel's research focused exclusively on women. Kegel theorized that the weakening of this muscle could be the underlying cause of both the genital relaxation and the incontinence that so many of his patients were experiencing. He reasoned that as this was a muscle, it could be toned like any other muscle of the body with the proper exercises.

Over many years Kegel worked with hundreds of patients to develop his technique, culminating in the 1948 publication of his article "A Nonsurgical Method of Increasing the Tone of Sphincters and Supporting Structures." The core of his method involved teaching women how to identify and contract their pubococcygeus muscle. He found that many women with a weakened pubococcygeus could not easily identify it and to assist them he and his wife developed a device they named a perineometer. The perineometer consists of a cylinder of rubber on a metal stem attached to a manometer (a device that measures pressure). The perineometer was inserted into the vagina, and the manometer indicated the pressure exerted when the pubococcygeus was contracted. In this way, women could monitor their own success until they could reliably identify and contract their pubococcygeus without assistance. Kegel prescribed his patients to exercise the muscle for twenty minutes at a time, three times a day for best results.

While Kegel's research focused on women, Kegel exercises are often prescribed to treat incontinence in men as well. The exercises have also been reported to improve sexual function in both sexes.

Description

Generally speaking, both women and men share the same health problems. However, several conditions and diseases affect women differently, either because they experience different symptoms or because the disease may be more common in women, such as **osteoarthritis** after age 45, **obesity**, and depression. Other conditions, such as **menopause** and **pregnancy**, are unique to women. Another factor in women's health is consideration of the health consequences of discrimination against women that exist in nearly all cultures.

In the United States, the average life expectancy is nearly five years longer for women than men (80.9 years for women and 76 years for men). Because of the gender gap in lifespan, women represent approximately two-thirds of the population older than 65 and three-fourths of the population aged 85 years and older. The reasons for this variance are primarily the physiological differences among men and women.

WWW.BOOKBAZ.IR

According to the Centers for Disease Control, the leading causes of death for women in the United States, as of the most recent data year, which is 2010, are as follows:

- Heart disease (23.5%)
- Cancer (22.1%)
- Stroke (6.2%)
- Chronic lower respiratory diseases (5.9%)
- Alzheimer's disease (4.7%)
- Unintentional injuries (3.6%)
- Diabetes (2.7%)
- Influenza and pneumonia (2.1%)
- Kidney disease (2.1%)
- Septicemia (1.5%)

Lifestyle issues such as **smoking**, alcohol intake, diet and **exercise** influence risk of death due to **heart disease**, cancer, **stroke**, chronic lower respiratory disease, and type 2 diabetes. A study released in 2013 found that the incidence of heart disease per 1,000 post-menopausal women was 3.3 in those who never smoked, 3.7 in former smokers, 7.6 in current smokers, and 5.3 who had recently stopped smoking. Even after changes in weight, these figures did not change.

During different phases of a woman's life cycle, there are complex interactions between sex hormones, physiological changes, and emotional issues. Physiological changes occur as early as embryonic development when hormones program structural differences between male and female brains. During reproductive years, sex hormones profoundly influence reproduction and development, which creates a spectrum of gender-specific health issues. With advancing age and onset of menopause, women's risk of disease becomes generally similar to men's. Although the same disease may affect women and men equally, biological mechanisms and psychosocial differences can influence the clinical course of a disease differently in women. The number of women working has doubled within the past 50 years. The effect of work **stress**, new environmental exposures and multiple roles is expected to have a health and social impact. For example, women are often more stressed than men at work, due to the high demands of having to combine work and family responsibilities.

Hormone replacement therapy treatments may be a part of a women's life throughout the life cycle, whether she is taking birth control pills or other forms of hormones (such as an **intrauterine device** with hormones) to prevent pregnancy, or hormone treatments to achieve pregnancy, followed by hormone treatments to relieve the symptoms of menopause. Menopausal hormone replacement therapy is associated with controversy regarding its risks versus benefits. A Women's Health Initiative study released in 2013 found that the risks and benefits of such therapy is complicated. Women should discuss this topic in depth with their healthcare provider. To determine if the benefits outweigh the risks.

Cancers of various types comprise the most common causes of premature death among women. **Breast cancer** is the second leading cause of death in women and the most commonly diagnosed cancer. Lung cancer, secondary to cigarette smoking is the leading cause of cancer death among women.

Cerebrovascular disease accounts for approximately 6% of all deaths in women and it is the third leading cause of mortality. The least common form of stroke in the general population, **subarachnoid hemorrhage**, is more common in women.

The prevalence of cigarette smoking has steadily increased greatly in women in the United States and this is correlated with pulmonary disease. Death rates for pulmonary disease including cancer and infectious causes of death are expected to rise for women. According to the 2012 CDC data, one out of six American women ages 18 and up smoke cigarettes and smoking accounts for the deaths of more than 200,000 women in the United States each year. A 2013 survey indicated that more than one-fifth (21%) of twelfth grade girls had used hookah in the year prior to the survey. Another trend is the use of e–cigarettes, which 10% of high school girls have tried at least one time.

Diabetes, a leading cause of death in women is more prevalent among Hispanic, African–American, and Native American women. Past age 45, diabetes affects about one in six women.

Women are more vulnerable to psychological disorders, such as depression, a serious affective disorder whereby the prevailing emotional mood interferes with quality of life and normal functioning. **Postpartum depression** is specific to women and is diagnosed when a new mother develops a major depressive episode within one month after giving birth. Other psychological disorders include **eating disorders**, such as **anorexia nervosa** and bulimia, which are much more prevalent in teenage girls and young women than in boys and young men.

Other health issues affecting women include:

- Osteoporosis, or loss of the quantity of bone, common in postmenopausal women.
- Alcohol abuse, which can have adverse effects on fertility and in the developing fetus (fetal alcohol syndrome). Women frequently do not seek treatment

because of fear of consequences (i.e., loss of child custody).

- Acquired immunodeficiency syndrome (AIDS), which represents the highest percent increase in the death rates of women.
- Violence is a major issue and a leading cause of death, primarily from a perpetrator who is or was a partner.

Demographics

A number of diseases affect women at a disproportionately high rate and the prevalence of some diseases is also increasing in women. For example, the latest World Health Organization (WHO) and UNAIDS estimations suggest that women in sub-Saharan Africa make up 60% of the people in that region who have HIV. The WHO also reports that violence in women around the world, which impacts 10–60&percnt of women in the 15–49 years age group, puts them at higher risk for HIV. According to the Centers for Disease Control and Prevention (CDC), between 2000 and 2004, the estimated number of **AIDS** cases in the United States increased 10% among women compared to 7% in males. In 2004, women accounted for 27% of the 44,615 newly reported AIDS cases among adults and adolescents. HIV affects African-American and Hispanic women to a higher degree. Even though they represent less than 25% of all women in the United States, they account for more than 79% of AIDS cases in women. Worldwide, more than 90% of all adolescent and adult HIV infections have resulted from heterosexual intercourse. Women are particularly vulnerable to heterosexual HIV transmission as a result of substantial mucosal exposure to seminal fluids. This increases the risk of HIV transmission when coupled with the high prevalence of non-consensual sex, sex without condom use, and the high-risk behaviors of their partners.

Heart disease also ranks high in women's health issues, and is the most common cause of death for women of all ages in the United States. It is responsible for more deaths in women than all forms of cancer combined. Heart disease is the most significant health concern for women in the United States, causing nearly 300,000 deaths each year and accounting for one in four deaths for women. Nearly two-thirds of women who die suddenly as a result of heart disease experienced no symptoms prior to the fatal attack.

The third leading cause of cancer death for women in the United States is colorectal cancer. Colorectal cancer is often mistakenly thought of as a man's disease, but equal numbers of men and women die of colorectal cancer each year.

Nearly 160,000 people in the United States die of stroke each year, and almost two-thirds of them are women. Stroke not only ranks as women's third killer, but it is also one of the leading causes of women's disability in the United States.

Chronic lung conditions, including **bronchitis** and **emphysema**, kill approximately 65,000 women in the United States each year. The main cause is smoking, strongly associated with lung cancer.

More women than men have Alzheimer's disease. Some 45,000 women die with Alzheimer's disease each year, more than twice the number of men. One reason more women may be affected is that women generally live longer, and the risk of Alzheimer's increases with age.

Autoimmune diseases, which include **systemic lupus erythematosus** (SLE), **rheumatoid arthritis**, and **multiple sclerosis**, represent another health issue for women. Although many autoimmune diseases are rare, collectively these chronic diseases afflict 5–8% of the U.S. population and affect women at much higher rates. For example, 90% of the nearly two million Americans diagnosed with (or suspected of having) SLE are women.

Chronic fatigue syndrome (CFS) is another disorder that is diagnosed two to four times more often in women than in men.

An estimated 15 million new cases of sexually transmitted diseases (STD) occur in the United States each year. Some STDs such as **syphilis** have declined in women, while others (e.g., **genital herpes**, **gonorrhea**, chlamydia) continue to spread through the population, posing a significant health problem for women. This is because symptoms in women are minor or nonspecific, especially in the early stages. The result is that STDs in women sometimes are not diagnosed until late in the disease. STDs that occur during pregnancy can affect the fetus or newborn. About one-quarter to one-half of women infected with an STD during pregnancy give birth to either premature or low birth weight infants. In about one-third to two-thirds of these pregnancies, the infection is passed to the infant, possibly causing permanent disabilities.

Psychological and affective disorders are more prevalent in women. Major depression and dysthymia affect twice as many women as men. This two-to-one ratio exists regardless of racial and ethnic background or economic status. The same ratio has been reported in 10 other countries all over the world. Men and women have about the same rate of **bipolar disorder**, although its course in women typically has more depressive and fewer manic episodes. A greater number

WWW.BOOKBAZ.IR

of women have the rapid cycling form of bipolar disorder, which may be more resistant to standard treatments. As for postpartum depression, it is estimated that 10–15% of women experience it after giving birth. As for eating disorders, the American Anorexia/Bulimia Association reports that more than 1,000 women and girls die of anorexia each year and more than 90% of people with anorexia are adolescent and young women.

Causes and symptoms

Cardiovascular disease can be caused by blockage of a blood vessel, high blood pressure, or a secondary complication to another disease. There may be an abnormal heart rhythm or cell death. Patients may complain of a broad spectrum of symptoms that may include **pain**, chest discomfort, high blood pressure, or strain during physical exertion.

Cerebrovascular disease may cause **tremors** (shaking), loss of balance and coordination, or functional and sensation loss in some parts of the body. Patients may have sudden transient strokes that could result in temporary loss of consciousness and **amnesia** of the incident. Patients may also develop chronic neurological states that causing **memory loss** and behavioral changes (Alzheimer's disease).

When attempting to define the cause and symptoms of cancer, it is important to assess the type of cancer and location. Additionally, whether the tumor is localized (benign) or has spread to other areas (malignant) is vital for treatment planning and overall prognosis. In cases of breast cancer there may be a lump discovered during self-examination or **mammography** (special breast x rays). A study released in 2014, reported that screening mammograms are correlated with an overall reduction in breast cancer mortality of 19% when offered routinely in the United States.

Patients with pulmonary (lung) cancer may develop **shortness of breath**, **fatigue**, weight loss, worsening **cough**, and coughing up bright red blood with sputum. Lung infections such as **pneumonia** may present with high **fever**, weakness, difficulty breathing, and abnormal breath sounds heard with a stethoscope during **physical examination**.

Diabetes is a syndrome with disordered metabolism and high blood sugar due to an abnormality in the chemical that regulates sugar levels. It is characterized by an increased thirst, urination, and chronic skin infections.

Osteoporosis may cause the bones to be brittle and weak. Bone density screenings are used to detect changes in bone structure. According to an article published in 2012 in the *Journal of the American Medical Association,* half of the postmenopausal women in the United States who are age 50 and up will have a bone fracture due to osteoporosis at some point in their lives.

An alcohol abuser will continue to drink despite negative repercussions. The person may not seek treatment to evade legal and/or child custody problems. The patient may hide alcohol, or confine drinking to specific times. The disease progresses to where there may be permanent liver damage, memory blackouts, and **malnutrition**.

Depression is characterized by a combination of symptoms that interfere with the ability to work, sleep, study, eat, and enjoy once-pleasurable activities.

Patients with AIDS may not have symptoms for years. When active disease occurs, patients typically develop recurrent infections that are the usual cause of death.

Domestic violence is usually associated with a perpetrator who is in a relationship with the affected person. **Abuse** can be manifested by physical violence and/or homicide.

Diagnosis

Diagnosis can be accomplished with a history, physical examination, and specialized tests or procedures.

Tests

For cardiovascular disease, an electrocardiogram can determine the activity of the heart. Additional tests may include **echocardiography** (ultrasonic waves that generate an image), stress testing, and studies that require placing a catheter with a probe to examine the damage to heart tissue. Special tests may inject dyes to enhance visualization.

Cancer may be detected using specialized tests called **tumor markers** and imaging studies such as MRI and CAT scans. Cerebrovascular disease can be detected with a complete neurological examination and specialized imaging technology. Diabetes is usually detected by a careful history, presence of risk factors (obesity), and blood analysis of glucose levels. Osteoporosis can be evaluated with specialized bone densitometry.

Alcohol abuse can be established by a bio-psychosocial assessment and standardized tests that screen for this disorder. Psychological evaluation (such as the **Minnesota Multiphasic Personality Inventory**, MMPI) can usually detect depression or eating disorders. AIDS can be established by a careful history, belonging to high-risk

KEY TERMS

Alzheimer's disease—A progressive neurologic disease of the brain that leads to the irreversible loss of neurons and dementia.

Anorexia nervosa—Starving oneself to reduce body weight below the minimum level required to maintain health.

Antidepressant—A drug used to treat depression.

Bulimia—Eating excessively large amounts of food followed by vomiting or other forms of purging and stomach emptying.

Cardiovascular disease— A structural or functional abnormality of the heart, or of the blood vessels supplying the heart, that impairs its normal function.

Cerebrovascular disease—Disorders affecting the blood vessels that supply the brain that may result in a stroke.

Chlamydia—Small pathogens associated with pneumonia, abortion, diarrhea, conjunctivitis, arthritis, and encephalitis.

Dysthymia—Type of affective disorder or mood disorder that often resembles a less severe, yet more chronic form of major.

Electrocardiogram—An instrument that monitors heart rate and rhythm.

Emphysema—A chronic, irreversible disease of the lungs.

Estrogen—A hormone secreted by the ovaries that affects many aspects of the female body, including a woman's menstrual cycle and normal sexual and reproductive development.

Estrogen replacement therapy—Use of the female hormone estrogen to replace that which the body no longer produces naturally after medical or surgical menopause.

Genital herpes—A sexually transmitted disease caused by the herpes simplex virus.

Gonorrhea—A sexually transmitted infection caused by the bacterium *Neisseria gonorrhoea*.

Menopause—The time of life when a woman's menstrual periods stop. A woman is in menopause when she has not had a period for 12 months in a row.

Osteoporosis—A decrease in bone density.

Postmenopausal—A term referring to the time period following menopause.

Stroke—The sudden death of some brain cells due to a lack of oxygen when the blood flow to the brain is impaired by blockage or rupture of an artery to the brain.

Syphilis—A sexually transmitted disease caused by the bacterium *Treponema pallidum*.

groups and Western blot analysis (examination of blood to detect the protein of human **immunodeficiency** virus). Violence can be established by physical signs of beating, such as cuts and **bruises**.

Treatment

Treatment depends on the extent of disease and the present health status of the patient. In some cases, treatment may stopped or it may altogether be refused.

Treatment for cardiovascular disease may include surgical intervention and/or conservative medical treatment with medications. Diet, exercise, and weight reduction are important parameters for treatment planning. Appropriate referrals, counseling, and follow-up are usually indicated. Treatment for cancer may include a combination of surgery, **chemotherapy**, or **radiation therapy**. These treatment modalities may be given singly or in combination different times during disease progression. Cerebrovascular disease can be treated surgically and/or with medications that thin the blood. Symptomatic care may be indicated in addition to close monitoring if the patient develops disability and/or cognitive impairment.

Diabetes can be treated by dietary modifications and medications, which treat abnormal levels of blood glucose (sugar). Osteoporosis can be treated with estrogen replacement therapy and regular vitamin/mineral intake. Alcohol abuse may require long-term therapy, inpatient treatment and medications. Community-centered support group meetings are also recommended as a form of treatment maintenance.

To date there is no treatment for AIDS, other than medications that offer symptomatic relief. Alcohol abuse, psychological disorders, and violence require therapy, possible medication, and community centered support group meetings.

Family planning

Women may consider a number of options for family planning:

WWW.BOOKBAZ.IR

- Natural family planning, in which the couple tracks the woman's ovulation and either avoids sexual intercourse during ovulation or uses a barrier method of contraception during that time.
- Barrier methods prevent sperm from entering the uterus. Examples are the diaphragm, cervical cap, contraceptive sponges, and condoms.
- Hormone treatments prevent ovulation. Examples are the birth control pill, birth control patch, vaginal ring, hormone injections, and a form of IUD (intrauterine device.)
- Non-hormonal IUD is made of copper and has no hormonal component.
- Sterilization includes tubal ligation, which closes the fallopian tubes to prevent eggs from traveling to the uterus.

A woman should discuss with her healthcare providers the options that are recommended for her.

Alternatives

There are numerous studies that support intake of co-enzyme Q10 for cardiovascular health in some people (e.g., those with chronic disease of the heart muscle). Some studies indicate positive results for reproductive health using **acupuncture**. Certain herbs may be beneficial during menopause. However, published scientific evidence is often lacking.

Clinical trials

Many clinical trials for the study and treatment of women's health are currently sponsored by the National Institutes of Health (NIH) and other agencies. Clinical trial information is constantly updated by NIH.

Prognosis

The prognosis depends on the extent of disease and the physical and emotional status of the patient. Prognosis is also related to tolerance of treatment, adverse drug effects, complication during or after surgery, disease resurgence, and patient compliance with treatment recommendations.

Prevention

One of the most reliable measures of prevention is education and training. The Council on Graduate Medical Education and several institutes of the NIH have provided funding for numerous centers to research women's health issues. On a more individual level, preventive and personal habits are vital for good health. Most physicians believe that a baseline physical examination is a reliable comparative tool. Women should receive counseling for health issues such as smoking, exercise, diet, primary disease prevention, safe sexual practices, alcohol abuse, psychological disorders, and violence. Knowledge of family history is important since many diseases have a strong propensity among first-degree relatives. Blood pressure should normally be measured every other year after the age of 20. Screening tests for breast, cervical, and colorectal cancer is recommended. Pap smears taken during routine pelvic examinations can screen for disease processes in the reproductive tract. Serum **cholesterol** monitoring and reduction if necessary are advised. Patients may require postmenopausal estrogen replacement therapy and vitamin/mineral supplements.

Monique Laberge, PhD
REVISED BY RHONDA CLOOS, RN

Women's nutrition

Definition

Women's **nutrition** addresses the dietary requirements of females after they reach adulthood. Nutritional needs change over time due to factors such as menstruation, **pregnancy**, **lactation**, **menopause**, and **aging**.

Purpose

A nutritious diet and regular physical activity are part of a healthy lifestyle that promotes health and helps prevent chronic diseases such as type 2 diabetes, **heart disease**, high blood pressure (**hypertension**), high

WWW.BOOKBAZ.IR

cholesterol, **osteoporosis**, and certain cancers. Certain phases of a woman's life, such as pregnancy and menopause, have different nutritional requirements.

Description

As a woman ages, changes in the body occur that affect nutritional needs. After age 25, the basal metabolic rate (BMR) begins to decline. Metabolism is the process of the body converting food into energy. When metabolism slows, the body needs fewer calories to function. If calorie intake is not adjusted or any additional calories are not expended through physical activity, the resulting imbalance causes weight gain. Continued weight gain further slows the BMR, reducing overall calorie requirements.

The BMR is based on factors including size and particularly muscle mass. People who are larger or have more muscle mass use more calories than those who are smaller or have less muscle mass. Women have more body fat than men, so they generally require fewer calories than men of the same age and weight. Muscle mass tends to decline with age—after age 30, muscle mass decline occurs at a rate of 3% or more per decade. Failure to **exercise** muscles can result in a loss of up to 30%–40% of muscle strength by the time a person is 65.

Bone density also decreases with age, starting after age 40. The decline accelerates after menopause, which is when a woman's period ends. Bone loss is accompanied by a loss in bone strength and an increased risk of osteoporosis, a condition described as "brittle bones." Bone loss leaves older women more vulnerable to bone **fractures**. Adequate **calcium** intake during a woman's younger years can help protect against bone loss later in life. Other factors contributing to osteoporosis include physical inactivity and **smoking**.

U.S. dietary guidelines

The U.S. Department of Agriculture's (USDA) *Dietary Guidelines for Americans 2010* contain the U.S. recommendations for healthy eating. The guidelines are represented by MyPlate, a graphic representation of the general daily recommendations for the five food groups. The graphic is of a plate divided into four sections—on one half are fruits and vegetables and on the other half are grains and proteins. To the side is a small circle representing dairy products.

Some of the MyPlate guidelines include:

- Fill half of each plate with fruits and vegetables. Recommended choices include red, orange, and dark-green vegetables such as tomatoes, sweet potatoes, and broccoli.
- Cut back on foods high in solid fats, added sugars, and sodium (salt).
- Vary protein food choices and keep meat and poultry portions small and lean. Beans are another good source of protein. People are advised to eat seafood at least twice a week, especially varieties that contain omega-3 fatty acids (such as salmon and tuna).
- Make half of all grains consumed whole grains. Examples include 100% whole-grain cereals, breads, crackers, rice, and pasta.
- Drink skim or 1% milk. These products have the same amount of calcium and other essential nutrients as whole milk but contain less fat and calories. Calcium-fortified soy products are an alternative.

Calorie requirements

The amount of calories required each day depends upon how active a person is, according to the *Dietary Guidelines*. The USDA provides general calorie recommendations for women based on age and activity level.

Women between the ages of 19 and 30 should consume approximately:

- between 1,800–2,000 calories if sedentary
- between 2,000–2,200 calories if moderately active
- 2,400 calories if active

Women between the ages of 31 and 50 should consume approximately:

- 1,800 calories if sedentary
- 2,000 calories if moderately active
- 2,200 calories if active

Women 51 or older should consume:

- 1,600 calories if sedentary
- 1,800 calories if moderately active
- between 2,000–2,200 calories if active

Macronutrients

All dietary calories come from macronutrients—carbohydrates, fats, and proteins. Macronutrients are dietary compounds that provide energy. Proteins and carbohydrates contain four calories per gram, and fat contains nine calories per gram. Alcohol is also considered a macronutrient and contains seven calories per gram. Carbohydrates serve as the primary source of fuel for the body. When food is consumed, the sugars and starches in carbohydrates are used (as glucose) for energy. Excess glucose is stored in the muscles as glycogen. If the glycogen reserves are not used, they are converted to fat, resulting in weight gain.

CARBOHYDRATES. Sources of healthy carbohydrates include vegetables, fruits, legumes, and whole grains. Other carbohydrates include sugars, starches, and fiber.

Soluble fiber is found in many vegetables and fruits. Other sources include legumes, barley, oats, and oat bran. Soluble fiber helps to slow digestion so that a person fills full for a longer period of time. This sense of fullness, known as satiety, helps with appetite control and weight loss. Soluble fiber also helps to decrease cholesterol levels, which lowers the risk for heart disease. Insoluble fiber is found in vegetables such as green beans, wheat and other grains, and the skins of vegetables and fruits. This fiber, which is known as roughage, helps to prevent **constipation**.

FATS. Because fats contain more calories than protein or carbohydrates, people should choose healthy fats and consume them in limited amounts. Healthier fats include monounsaturated or polyunsaturated fats. These unsaturated fats help to reduce blood cholesterol levels. Saturated fats and *trans* fats, on the other hand, promote heart disease if consumed in high amounts.

PROTEIN. Protein is the major functional and structural component of every cell in the body. Proteins are composed of amino acids, nine of which cannot be synthesized to meet the body's needs. These amino acids must be obtained from the diet. Food proteins, known as dietary proteins, include meat, eggs, seafood, beans and peas, nuts, seeds, and soy products. The quality of a source of dietary protein depends on its ability to provide the nitrogen and amino acid requirements needed for growth, maintenance, and repair.

ALCOHOL. Women should limit their alcohol consumption to one drink per day, according to the *Dietary Guidelines*. Heavy drinking and **binge drinking** are associated with adverse health effects. According to the Mayo Clinic, examples of one drink include:

- 12 fluid oz. (355 mL) of beer
- 5 fluid oz. (148 mL) of wine
- 1.5 fluid oz. (44 mL) of distilled spirits (80 proof)

Some studies have indicated that regular alcohol consumption may have health benefits, such as a reduced risk of developing heart disease. According to the Mayo Clinic, these benefits may only apply to older adults or those with existing risk factors for heart disease, such as high cholesterol. For younger and middle-aged women, the risks of regular alcohol consumption (in excess of recommendations) could outweigh any potential benefits.

The Mayo Clinic advises woman who drink alcohol to talk to their doctors about taking folate (**folic acid**) supplements to help reduce the risk of **breast cancer** associated with alcohol use.

RECOMMENDED INTAKES. The recommended dietary reference intakes (DRIs) for adults are that 45%–65% of daily calories should come from carbohydrates, 10%–35% from protein, and 20%–35% from fat. People should limit intakes of dietary cholesterol, *trans* fats, and saturated fats. The recommended adequate intake (AI) levels for omega-3 fats are 1.1 grams for women 19 and older (including pregnant women) and 1.3 grams for **breastfeeding** women. The AI for omega-6 fats is 12 grams for women aged 19–50, 11 grams for women 51 and older, and 13 grams for pregnant or breastfeeding women.

The AI for fiber is 14 grams per 1,000 calories, or 25 grams per day for women. Most people in the United States do not consume enough dietary fiber, and usual intake averages around only 15 grams per day. To meet the recommendations for fiber, women should increase their consumption of beans and peas, vegetables, fruits, and whole grains. Whole grains can vary in fiber content, so consumers should check the nutrition facts label to find out a product's fiber content.

Vitamins and minerals

The *Dietary Guidelines* identify four nutrients of concern that tend to be lacking in the typical American diet, due to low consumption of vegetables, fruits, whole grains, milk and milk products, and seafood. These nutrients are calcium, **vitamin D**, potassium, and dietary fiber.

CALCIUM AND VITAMIN D. **Diets** low in calcium and vitamin D may increase the chance of developing osteomalacia and osteoporosis, characterized by weak or brittle bones. Good nutrition and weight-bearing exercise, such as walking, hiking, or climbing stairs, help to build and maintain bones.

Good sources of calcium include low-fat dairy products such as cheese, yogurt, and milk; canned fish with bones, such as salmon and sardines; dark green leafy vegetables; and calcium-fortified foods such as orange juice, bread, and cereal. The recommended intake of calcium for women ages 19–50 is 1,000 mg per day. Pregnant and lactating women need 1,000 mg per day. Women above the age of 50 should consume 1,200 mg of calcium per day.

Women can obtain vitamin D in three ways: from sunlight on the skin, from the diet, and from supplements. Experts recommend a daily intake of 600 IU of vitamin D up to age 70. After age 70, women should

WWW.BOOKBAZ.IR

increase their uptake to 800 IU daily. This can be obtained from supplements or vitamin D-rich foods such as egg yolks, saltwater fish, liver, and fortified milk. The Institute of Medicine recommends no more than 4,000 IU per day for adults. Doctors may prescribe higher doses for people who are deficient in vitamin D.

POTASSIUM AND SODIUM. Dietary potassium can help lower blood pressure by reducing the adverse effects of **sodium**. Other possible benefits of a diet rich in potassium include a reduced risk of developing **kidney stones** and decreased bone loss. The *Dietary Guidelines* recommend that U.S. adults should consume no more than 2,300 mg of sodium per day. This drops to 1,500 mg per day for people aged 40 or older, people with high blood pressure, and African Americans, who are at higher risk for hypertension. According to the Centers for Disease Control and Prevention, 69% of U.S. adults fall within these categories.

The AI for potassium for adults is 4,700 mg per day. Dietary sources of potassium include bananas, white beans, plain yogurt, baked potatoes, and clams.

Special concerns

Dietary recommendations change throughout a woman's life. Phases that have special nutritional considerations include menstruation, pregnancy, and menopause.

MENSTRUATION. Diet may help control symptoms of **premenstrual syndrome** (PMS). Some research indicates that calcium could help to regulate mood-related chemicals in the brain and to lower fluid retention, according to the Academy of Nutrition and Dietetics. The Academy advises women to consider increasing their calcium intake, especially since the mineral is essential to bone health. The Academy also recommends limiting sodium intake to 2,300 mg per day to prevent water retention (bloating). Women should not reduce water intake, as proper hydration is important to good health.

Because of the blood lost during menstruation, iron is an important mineral in a woman's diet. Low iron can result in iron-deficiency anemia, a condition characterized by low red blood cell count. The recommended dietary intake for iron is 15 mg per day for women aged 14–18; this increases to 18 mg for women aged 19–50 and then drops to 8 mg for women 51 and older. Pregnant women require 27 mg of iron daily.

PREGNANCY. Good nutrition is important during pregnancy and breastfeeding, as there is an increased need for calories and for many nutrients. A particularly important nutrient during pregnancy is folic acid, which is one of the B **vitamins**. Folic acid reduces the chance of having a baby with brain or spinal cord defects. Experts recommend that women of childbearing age consume 400 micrograms (mcg) of folic acid every day. Pregnant women should consume 800 mcg per day. Good sources of folic acid include dark green leafy vegetables, oranges and orange juice, dried beans and peas, and folate-fortified breads and cereals. The World Health Organization has expressed concern about pregnant women in areas of Africa and Southeast Asia having **vitamin A** deficiency, which can lead to blindness in children.

Omega-3 fatty acids may play a role in infant visual and cognitive development. The *Dietary Guidelines* recommend that women who are pregnant or breastfeeding consume 8–12 oz. of a variety of seafood each week. Women should be cautious, as some types of fish—especially tilefish, shark, swordfish, and king mackerel—have high levels of mercury. Women can consult with their physicians if they are unsure about which types of fish are safe to eat. The Mayo Clinic advises women to avoid raw fish and shellfish, particularly oysters and clams, as well as fish caught in polluted water.

Women who may become pregnant or are pregnant should avoid alcohol. After the baby is born, alcohol should not be consumed at all until consistent latch-on and breastfeeding patterns are established. Women should then wait at least four hours after drinking alcohol before breastfeeding.

MENOPAUSE. Perimenopause refers to the time leading up to menopause. This usually occurs when a woman is in her 40s, although it may happen earlier or later. Hormone fluctuations could cause irregular periods and symptoms like hot flashes and night sweats. Menopause occurs when menstruation ceases for 12 consecutive months. After 12 months, a woman is considered post-menopausal.

During the stages of menopause, women may gain weight and see an increase in body fat around the abdomen. Exercise and diet can help prevent weight gain and relieve symptoms of menopause.

The Academy of Nutrition and Dietetics recommends that women in their mid- to late 40s reduce their daily calorie intake by 200 calories. Healthy food choices include calcium-rich foods, fruits, and vegetables, which are also sources of fiber. The risk of breast cancer rises by 20% when women gain more than 20 lb. (9.08 kg) after menopause, according to the Academy. That risk goes back down when women lose that weight.

KEY TERMS

Adequate intake (AI)—Recommendations for vitamins and minerals that are established when there is not enough evidence to determine an RDA.

Body mass index (BMI)—Determines whether a person is at a healthy weight, underweight, overweight, or obese. BMI is calculated by squaring height (in inches) and dividing by weight, then multiplying that number by 703. The metric formula for the BMI is the weight in kilograms divided by the square of height in meters.

Cardiovascular disease—Refers to diseases of the heart and circulatory system (blood vessels) such as angina, heart attack, and stroke.

Folate—One of the B vitamins, also called folic acid.

Hypertension—High blood pressure.

Iron-deficiency anemia—The inability to make sufficient red blood cells, resulting in fatigue, shortness of breath, headaches, and an inability to fight infections. It is common in pregnancy.

Menopause—Phase in a woman's life during which ovulation and menstruation end.

Osteomalacia—Mild thinning of bone mass. Osteopenia results when the formation of bone is not enough to offset normal bone loss. Osteopenia is generally considered the first step to osteoporosis.

Osteoporosis—Thinning of the bones with reduction in bone mass due to depletion of calcium and bone protein. Osteoporosis predisposes a person to fractures, which are often slow to heal and heal poorly. It is more common in older adults.

Recommended dietary allowance (RDA)—The average daily dietary intake level that is sufficient to meet the nutrient requirements of nearly all (approximately 98%) healthy individuals.

Type 2 diabetes—Type of diabetes in which the pancreas either does not make enough insulin or cells become insulin resistant and do not use insulin efficiently.

Precautions

Diets low in calcium, vitamin D, or magnesium or high in **caffeine**, alcohol, sodium, or protein may increase the chance of developing osteomalacia and osteoporosis. Good nutrition and weight-bearing exercise, such as walking, hiking, or climbing stairs, helps to build strong bones and prevent bone loss.

Women should consult their doctors before beginning a diet or exercise program.

Complications

Of the many diseases that may affect women, five have a scientific-based connection to nutrition: iron-deficiency anemia, osteoporosis, heart disease, type 2 diabetes, and some types of cancer.

Chronic diseases

As women age, the risk of developing chronic disease increases. Women over age 45 who are overweight, physically inactive, and have a family history of diabetes are more likely to develop type 2 diabetes. Maintaining a healthy weight, eating a varied and balanced diet, and engaging in an active lifestyle can reduce this risk.

Women are at a higher risk of developing osteomalacia and osteoporosis than men are. There are many factors that contribute to this disease, including genetics, diet, hormones, age, and lifestyle factors. The disease usually has no symptoms until a fracture occurs.

Breast cancer is the most common type of cancer among American women other than **skin cancer**. Obese, sedentary women are more likely to develop breast cancer, and dietary factors may possibly play a role in its development. Some studies suggest that excessive fat intake may increase breast cancer risk, either by raising estrogen levels or by altering immune function. Diets that include adequate amounts of fruits, vegetables, and fiber-rich foods may help protect against breast cancer. However, controversy exists as to whether diet is actually a contributing factor. Excessive alcohol consumption may raise the risk of breast cancer in women.

According to the American Heart Association, more than one in three women has cardiovascular disease (CVD). There are many forms of heart disease. According to the CDC, risk factors for heart disease include high cholesterol, hypertension, diabetes, **obesity**, poor diet, alcohol use, and physical inactivity.

Obesity and overweight

Obesity is defined as an abnormal accumulation of body fat. It is usually determined by the **body mass**

WWW.BOOKBAZ.IR

index (BMI), a measurement for adults based on height and weight. A BMI of 18.5–24.9 is considered a normal weight, a BMI of 25–29.9 is considered overweight, and a BMI of 30 or higher is considered obese. Waist size is also a measure of health. Abdominal weight, also known as belly fat, places people at risk for conditions such as high blood pressure, type 2 diabetes, and heart disease. A person can have a normal BMI but a high proportion of abdominal fat. A waist measurement of 35 in. (89 cm) or more indicates an unhealthy concentration of belly fat in women.

Obesity is considered an epidemic that affects all age groups in the United States. According to the CDC, 35.7% of adults aged 20 and older were obese in 2009–2010. The USDA reports that up to 64% of women are considered overweight or obese.

Obesity also is a problem around the world. Although both sexes have shown higher rates of overweight and obesity in recent years, obesity rates are higher for women around the world, according to the World Health Organization. On the other hand, **malnutrition** and deficiency of important nutrients for women, and particularly for pregnant women, is a problem in many countries around the world.

Beth Fontenot, AM
REVISED BY TERESA G. ODLE,

Wound care

Definition

Wound care involves cleaning a wound, flushing or irrigating it with pressurized water or an antiseptic solution, and applying or changing a dressing.

Purpose

Prompt, appropriate care helps **wounds** heal properly and prevents infections with **tetanus** or other bacteria or fungi, which can be major health threats. Flushing or irrigation of a wound removes debris and dead (necrotic) tissue and reduces the risk of infection or treats an existing infection. Irrigation promotes proper healing and helps prevent the surface of a wound from healing over an infected area. Wound irrigation is particularly important for bites, lacerations, and crush injuries, which often become infected due to the presence of dead tissue and foreign debris, such as splinters or dirt. For acute injuries, such as a crushing wound or knife cut, the wound is flushed immediately, before the injury is stitched closed. Care of wounds or open sores is performed by specialized wound-care nurses, doctors, dentists, oral surgeons, or the patients themselves.

Surgical sites are irrigated with antibacterial solution immediately before stitching the wound closed. Wound irrigation may also be performed after surgery to prevent or treat infection. Surgical wounds sometimes open up along part or all of the incision—wound dehiscence. Rather than re-close such wounds with sutures or stitches, the patient may need to care for the wound at home until it heals. Since such wounds heal from the bottom up, dressings are used to soak up drainage (exudate) and dead tissue and to keep the skin from closing before the underlying tissue has filled in. Wound irrigation is also routinely performed by dentists or oral surgeons following tooth extractions, mouth **trauma**, or gum surgery, to cleanse the tooth socket and prevent mouth bacteria from entering the bloodstream.

About 15% of patients with diabetes develop diabetic foot **ulcers**, usually on the bottom of the foot. Approximately 6% of such patients must be hospitalized due to wound infection or other wound-related complications. Diabetic ulcers and other chronic wounds, such as **bedsores** or abscesses, may be irrigated periodically to treat or prevent infection.

Description

Wound care may be performed in a hospital, clinic, oral surgery center, or at home by a home health nurse or patients themselves. There is actually less risk of infection if wound care is performed at home because of the danger of **hospital-acquired infections**.

Immediate wound care includes:

- applying direct pressure to control any bleeding
- examining the wound for dirt and foreign objects after any bleeding has stopped

WWW.BOOKBAZ.IR

- cleaning the wound by gently flooding it with saline solution if available, with bottled water, or with clean running water
- gently cleansing the area around the wound with soap and clean water
- patting the area dry and covering it with an adhesive bandage or clean dry cloth
- leaving uncovered bites, punctures, and wounds that cannot be properly cleaned to prevent trapping bacteria that could result in infection

Irrigation and dressing

Wounds and ulcers heal faster and are less likely to become infected if they are kept covered and moist. The doctor will inform the nurse or patient how frequently wound dressings should be changed. To remove an old dressing:

- Any tape holding the dressing is carefully loosened.
- Wearing new, clean, non-sterile, medical gloves, the tape is carefully removed and the dressing is pulled off.
- If the dressing sticks to the wound, it can be wetted with warm water to loosen it unless instructed to remove it dry.
- Any gauze pads or packing tape are removed from inside the wound.
- The old dressing, packing material, and gloves are placed in a plastic bag for disposal.
- A gauze pad or clean, soft cloth is soaked in normal saline solution (physiologic or 0.9% sodium chloride) or mild soapy warm water and used to clean the wound and skin around the wound by gently dabbing or wiping the skin. All drainage, dried blood, or other material built up on the skin is removed. The wound should not bleed much. Skin cleansers, alcohol, peroxide, iodine, or antibacterial chemicals should not be used because these can damage the tissue and delay healing.
- The wound is rinsed with water and patted dry with a clean towel. It should not be rubbed.
- The wound is examined for foreign bodies, including pieces of dressing or suture materials, and for redness, swelling, a bad odor, and the color and amount of drainage.
- The gloves are removed and discarded with the old dressing, and the hands are washed.

To irrigate or flush out a wound:

- A new pair of non-sterile gloves are worn.
- A syringe is filled with physiologic saline solution or soapy water, according to the healthcare provider's instructions. Saline solution can be prepared at home by boiling 8 teaspoons (39 mL) of table salt in 1 gallon (4 L) of distilled water and cooling to room temperature.
- The syringe is held 1–6 in. (2.5–15 cm) away from the wound and sprayed forcefully enough into the wound to remove drainage and discharge. Saline forced through a 19-gauge catheter with a 35-mL syringe can achieve a pressure of about 8 psi.
- The wound is patted dry with a soft dry cloth or moist gauze.
- Lotions, creams, or herbal remedies should not be used on or around the wound without consulting the healthcare provider.
- Whirlpool treatment is used only for large and infected wounds.

To apply a new dressing:

- A new pair of non-sterile gloves are worn.
- Gauze pads and any packing tape are placed in a clean bowl containing normal saline solution. As the wound heals, it requires less gauze and packing material.
- The saline is squeezed from the pads and tape until they are no longer dripping—moist rather than wet. Wet-to-damp dressings promote autolytic debridement (removal of necrotic tissue by the body's enzymes), absorb exudate, and protect the surrounding normal skin.
- The pads or tape are inserted so as to carefully fill the wound and any spaces under the skin, according to the healthcare provider's instructions. The gauze or tape should not touch any healed skin.
- In addition to dressings, medications may be applied to the wound. These range from normal saline to growth factors, ulcer dressings, and skin substitutes for healing foot ulcers.
- The gauze or tape is covered with a large dry dressing pad that is held in place with tape or rolled gauze.
- All used supplies are discarded in the waterproof plastic bag, which is closed securely, placed in a second plastic bag that is also securely closed, and discarded in the trash.
- The hands are rewashed.

Types of dressings

Although moist saline remains a common dressing, many new types of dressing materials have been introduced.

- Alginate dressings are made with seaweed extract. They are very absorbent and are used for wounds with large amounts of exudate. They contain guluronic and mannuronic acids for strength and calcium

and sodium for absorption and are attached with secondary coverage. Alginate ropes are used to pack deep exudative cavities or sinus tracts. Wounds must be thoroughly irrigated to remove all of the fibers.

- Hydrocolloid dressings are microgranular suspensions of natural or synthetic polymers, such as gelatin or pectin, that absorb exudate to form a gel. They are impermeable to oxygen, moisture, and bacteria. They are used to maintain moisture in wounds that are dry or have little exudate, to support autolytic debridement in dry wounds with necrotic tissue, and for clean, granulating wounds. A conformable, highly adherent dressing, such as a wafer hydrocolloid, is used for areas that are both very moist and difficult to dress. Extra-thin hydrocolloids can be used for such difficult-to-dress areas as an ulcer on the heel.
- Hydrofiber dressings are absorbent fiber pads or ribbons for packing deep wounds. They are very absorptive for exudative wounds. The hydrofiber combines with the exudate to produce a hydrophilic gel. Some types of hydrofiber dressings contain 1.2% ionic silver, which is a strong antibacterial agent, even against methicillin-resistant *Staphylococcus aureus* (MRSA) and vancomycin-resistant enterococci. Hydrofiber dressing are covered with a secondary dressing.
- Hydrogels are water- or glycerin-based semi-permeable hydrophilic polymers that are used for dry necrotic wounds. They absorb or release water according to the state of the wound and have cooling effects that may reduce pain. Hydrogels are attached with a secondary covering. Hydrogel sheets or other non-adhesive dressings are used for wounds surrounded by fragile skin.
- Low-adherence dressings are made of various materials for easing removal without damaging underlying skin. They are used for minor wounds such as skin tears or almost-healed chronic wounds.
- Polyurethane foams are absorptive and are used for cleaning granulating wounds with little exudate.
- Polyvinyl films, which are semi-permeable to oxygen and moisture but impermeable to bacteria, are used for wounds that are neither dry nor very exudative.
- Transparent films are acrylic adhesive dressings that easily conform to difficult areas such as the heel. They have little absorptive or hydrating activity, but may be permeable to vapor. They are used for clean, dry wounds with little exudate, to secure an underlying absorptive dressing, or to protect a wound in an area of high friction.
- Other types of dressings include hydroactive pastes and isotonic sodium chloride gels.

Dressings may be impregnated with various substances. Impregnated gauze used for very exudative wounds may require twice-daily dressing changes. Impregnated materials include:

- silver sulfadiazine for infected wounds
- bacitracin-zinc ointment or ionic-silver hydrofiber dressings if the patient is allergic to sulfa drugs
- Manuka honey from *Leptospermum*) trees to promote closure of difficult or chronic wounds
- chemical or enzymatic debriding agents for removing necrotic tissue following surgical debridement of the wound, including hypertonic saline gels, collagenases (enzymes that break down collagen, the fibrous protein of connective tissues such as skin), and papain urea

Preparation

Before immediate care for a minor wound, the hands should be washed with clean water and soap and covered with disposable latex gloves, if possible. Jewelry and clothing near the wound should be removed, and fingers should not touch the wound.

All required supplies should be collected and organized before irrigating a wound and changing a dressing. A doctor or nurse may inject the wound site with a local anesthetic before irrigation. The work area and hands should be cleaned with an alcohol-based cleaner or as follows:

- Jewelry is removed from the hands.
- The hands are wetted by pointing them down under warm running water.
- The hands and nails are washed with soap for 15–30 seconds.
- The hands are rinsed well and dried with a clean towel.

Aftercare

Aftercare is aimed at preventing infection. Patients with puncture wounds or contaminated wounds may require a tetanus booster shot. Dressings should never be reused. Any soiled laundry from wound care procedures should be washed separately from other laundry, possibly with bleach.

Sometimes a wound-drainage culture is used to test for bacteria, fungi, or viruses in open wounds from punctures, cuts, tears, or surgical incisions or abscesses. Abscesses require making a small incision in the skin to obtain pus or fluid from the wound. The tip of a sterile cotton swab or a syringe and small

WWW.BOOKBAZ.IR

KEY TERMS

Alginate—Colloidal substances from marine brown algae, especially giant kelp, that are used for wound dressings.

Antiseptic—Chemicals applied to the skin to destroy bacteria and prevent infection.

Autolytic—Self-digestion; breakdown of tissue by the body's own enzymes.

Debridement—The removal of cut, dead, or contaminated tissue.

Dehiscence—The opening of sutures from a surgical incision.

Dressing—The covering of a wound.

Exudate—Drainage from a wound; an exudative wound is one that drains fluid and pus.

Hydrocolloid—Dressing material that turns into a gel when combined with watery drainage.

Hydrogel—A water-based dressing material.

Hydrophilic—Dressing material that absorbs water.

Irrigation—Flushing or washing out a wound.

Necrotic—Dead tissue.

Normal saline—Physiological saline; a solution of 0.9% sodium chloride, the approximate salt concentrate of blood and tissues.

Tetanus—Lockjaw; a rare but often fatal infection caused by the bacterium *Clostridium tetani* that lives in soil, dust, and manure.

needle (needle aspiration) is used to remove the sample for culturing.

Risks

There is a risk of infection, especially if the wound was exposed to ocean water, standing water, soil, or sand. Crush injuries are at greater risk of infection than cuts. Dog bites or puncture with a dirty object pose special risks. Puncture wounds can contain clothing bits or dirt. A physician should be consulted if:

- Foreign material is embedded in the wound.
- Redness, soreness, or pain increases.
- Swelling or bleeding occurs.
- Pus appears.
- The wound becomes larger, deeper, dried out, or dark-colored.
- Drainage increases, becomes thick, tan, green, or yellow, or develops a bad odor.
- Fever of above 100°F (38°C) lasts more than four hours.

Other complications of wound care are rare, as long as the irrigation solution is appropriate and does not irritate the skin. Hydrogen peroxide can damage the skin or internal organs if used to irrigate the abdominal cavity after surgery.

Results

A wound will normally heal properly, from the inside out, without becoming infected.

Margaret Alic, PhD

Wound culture

Definition

A wound culture is a laboratory test in which microorganisms from a wound are grown in a special growth medium. It is done to find and identify the microorganism causing an infection in a wound or an **abscess**. If a microorganism is found, more testing is done to determine how to treat the infection.

Purpose

Wounds are injuries to body tissues caused by disease processes or events such as **burns**, punctures, and human or animal bites. Wounds or abscesses also occur within body tissues as a result of surgery or dental procedures. Wounds become infected when microorganisms from the outside environment, or from within the person's body, enter the open wound and multiply. A wound that is red, painful, swollen, and draining pus is probably infected. A **fever** following surgery indicates an infection at the site of surgery.

To enable healing and prevent the spread of infection to other body tissues, the infecting microorganisms must be killed. A wound culture discovers which type of microorganism is causing the infection and the best antibiotic with which to kill it. This is important as physicians have become less inclined to prescribe **antibiotics** until certain they are needed because of **antibiotic resistance** that has developed due to overuse of the drugs.

Description

A sample of material, such as pus or a portion of tissue, is taken from the wound, placed in a sterile container, and sent to the laboratory. In the laboratory, this material is spread over the surface of several different types of culture plates and placed in an incubator at body temperature for one to two days.

A Gram stain is done by staining the slide with purple and red stains, then examining it under a microscope. If many white blood cells and bacteria are seen, it is an early confirmation of infection. The color of stain retained by the bacteria (purple or red), their shape (such as round or rectangular), and their size provides valuable clues as to their identity, and helps the physician predict which antibiotics might work best even before the entire test is completed. Bacteria that stain purple are called gram-positive; those that stain red are called gram-negative.

Bacteria can be grouped into two categories: aerobes and anaerobes. Aerobes are bacteria that need oxygen to live; anaerobes live only where there is no oxygen. Deep wounds, closed-off from oxygen, are an ideal environment for an anaerobic infection to develop. Foul-smelling odor, gas, or **gangrene** at the infection site are signs of an infection caused by an anaerobic bacteria. Routine cultures typically only look for aerobic bacteria. If the physician tells the laboratory to include a culture for anaerobes, a portion of the wound sample will be put on culture plates, or in a tube of culture broth, and incubated in a special chamber without oxygen.

Bacteria present in the wound sample will multiply and appear as visible colonies on the plates, or as cloudiness in the tube of broth. They are identified by the appearance of their colonies, the results of biochemical tests, and information from Gram staining part of the bacterial colony.

A sensitivity test, also called an antibiotic susceptibility test, is also done. The bacteria are tested against different antibiotics to determine which will treat the infection by killing the bacteria.

If the physician thinks the wound may be infected with a mold or yeast, a fungal culture is also done. The wound sample is spread on special culture plates that are treated to encourage the growth of mold and yeast. Different biochemical tests and stains are used to identify molds and yeast.

Other more unusual microorganisms, such as *Mycobacterium leprae*, may be the cause of a wound infection. The physician must notify the laboratory to culture specifically for these more unusual microorganisms.

The initial Gram stain result is available the same day, or in less than an hour if requested by the physician. An early report, known as a preliminary report,

WWW.BOOKBAZ.IR

KEY TERMS

Aerobe—Bacteria that require oxygen to live.

Anaerobe—Bacteria that live only where there is no oxygen.

Normal flora—The mixture of bacteria normally found at specific body sites.

is usually available after one day. This report will tell if any microorganisms have yet been found, and, if so, their Gram stain appearance. For example, they may have the appearance of a gram-negative rod, or a gram-positive cocci (spherical shape). The final report, usually available in one to three days, includes complete identification, an estimate of the quantity of the microorganisms, plus a list of the antibiotics to which they are sensitive. Cultures for fungi and anaerobic bacteria may take two to three weeks.

Wound culture is also called soft tissue culture, abscess culture, or wound culture and sensitivity.

Preparation

A piece of the infected tissue is the best specimen. If this is not possible, the next best specimen is pus from the wound. Because many microorganisms normally live on skin and mucous membrane, the specimen must not be allowed to touch the area surrounding the wound.

The physician first cleans the surface of the wound using alcohol. Using a syringe, the physician suctions out (aspirates) as much pus as possible from the wound. Next, this is sent to the laboratory in a sterile container. If it is impossible to aspirate the pus, pus from within the wound can be collected on a swab.

The physician may choose to start the person on an antibiotic before the culture and sensitivity tests are completed. However, the specimen for culture should be collected before antibiotics are begun. Antibiotics in the person's system may prevent microorganisms present in the wound from growing in culture, and thus not be identifiable.

Results

A normal culture may be contaminated by a mixture of microorganisms normally found on a person's skin (normal flora).

It is not uncommon for the microorganism causing a wound infection to not grow in culture. This is particularly true if the specimen was collected with a swab rather than an aspirate or tissue biopsy.

Abnormal results

Streptococcus Group A, *Escherichia coli*, *Proteus*, *Klebsiella*, *Pseudomonas*, *Enterobacter*, Enterococci, *Staphylococcus aureus*, *Bacterioides*, and *Clostridium*, are common causes of wound infections. More than one microorganism may be the cause of the infection.

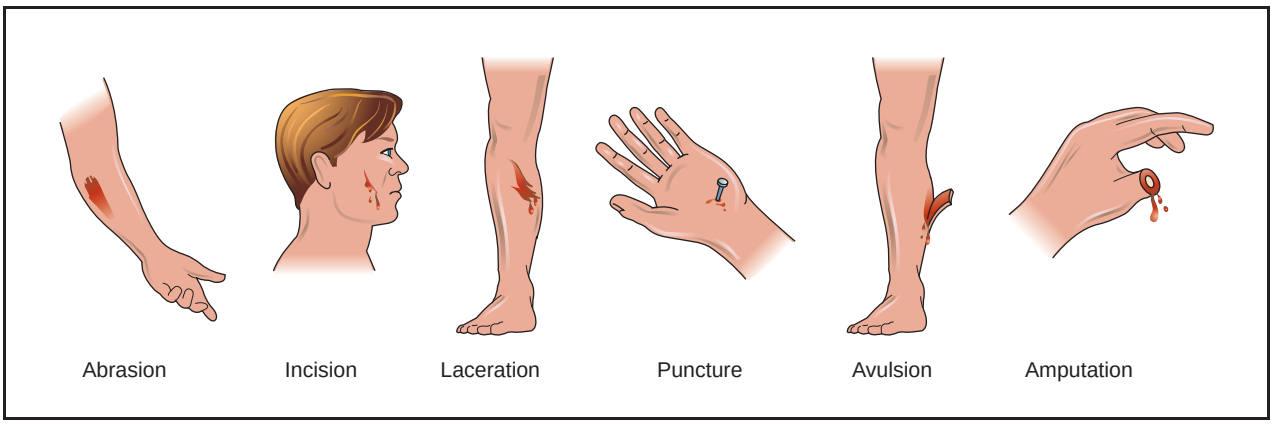
Wounds

Definition

A wound occurs when the integrity of any tissue is compromised (e.g. skin breaks, muscle tears, **burns**, or bone **fractures**). A wound may be caused by an act, such as a gunshot, fall, or surgical procedure; by an **infectious disease**; or by an underlying condition.

A close-up of a hard-contact gunshot wound with accompanying burn marks on the left and right sides of the wound. *(Custom Medical Stock Photo, Inc.)*



Examples of open wounds. *(Illustration by Electronic Illustrators Group. © Cengage Learning®.)*

Demographics

Wounds are very common. Nearly everyone has had a wound of one type or another. Minor wounds are especially common in childhood because children engage in so much play and activity. Annually, about 3.6 million Americans acquire some type of open wound requiring treatment by a healthcare provider, and an additional four million Americans are affected by a chronic wound.

Description

Types and causes of wounds are wide ranging, and healthcare professionals have several different ways of classifying them. They may be chronic, such as the skin **ulcers** caused by **diabetes mellitus**, or acute, such as a gunshot wound or animal bite. Wounds may also be referred to as open, in which the skin has been compromised and underlying tissues are exposed, or closed, in which the skin has not been compromised, but **trauma** to underlying structures has occurred (e.g. a bruised rib or cerebral contusion). Emergency personnel and first-aid workers generally place acute wounds in one of eight categories:

- Abrasions. Also called scrapes, they occur when the skin is rubbed away by friction against another rough surface (e.g. rope burns and skinned knees).
- Avulsions. These occur when an entire structure or part of it is forcibly pulled away, such as the loss of a permanent tooth or an ear lobe. Explosions, gunshots, and animal bites may cause avulsions.
- Contusions. Also called bruises, these are the result of a forceful trauma that injures an internal structure without breaking the skin. Blows to the chest, abdomen, or head with a blunt instrument (e.g., a football or a fist) can cause contusions.
- Crush wounds. Occur when a heavy object falls onto a person, splitting the skin and shattering or tearing underlying structures.
- Cuts. These are slicing wounds made with a sharp instrument, leaving even edges. They may be as minimal as a paper cut or as significant as a surgical incision.
- Lacerations. Also called tears, these are separating wounds that produce ragged edges. They are produced by a tremendous force against the body, either from an internal source as in childbirth, or from an external source like a punch.
- Missile wounds. Also called velocity wounds, they are caused by an object entering the body at a high speed, typically a bullet.
- Punctures. These are deep, narrow wounds produced by sharp objects such as nails, knives, and broken glass.

Causes and symptoms

Acute wounds have a wide range of causes. Often they are the unintentional results of motor vehicle accidents, falls, mishandling of sharp objects, or sports-related injury. Wounds may also be an intentional result of violence involving assault with weapons, including fists, knives, or guns.

The general symptoms of a wound are localized **pain** and bleeding. Specific symptoms include:

- An abrasion usually appears as lines of scraped skin with tiny spots of bleeding.
- An avulsion has heavy, rapid bleeding and a noticeable absence of tissue.
- A contusion may appear as a bruise beneath the skin or may appear only on imaging tests. An internal wound may also generate symptoms such as weakness, perspiration, and pain.

WWW.BOOKBAZ.IR

KEY TERMS

Abrasion—Also called a scrape. The rubbing away of the skin surface by friction against another rough surface.

Avulsion—The forcible separation of a piece of tissue from an entire structure.

Butterfly bandage—A narrow strip of adhesive with wider flaring ends (shaped like butterfly wings) used to hold the edges of a wound together while it heals.

Cut—Separation of skin or other tissue made by a sharp edge, producing regular edges.

Laceration—Also called a tear. Separation of skin or other tissue by a tremendous force, producing irregular edges.

Plasma—The straw-colored fluid component of blood, without blood cells.

Puncture—An injury caused by a sharp, narrow object deeply penetrating the skin.

Tourniquet—A device used to control bleeding, consisting of a constricting band applied tightly around a limb above the wound. It should only be used if the bleeding in life-threatening and cannot be controlled by other means.

Traumatic shock—A condition of depressed body functions as a reaction to injury with loss of body fluids or lack of oxygen. Signs of traumatic shock include weak and rapid pulse; shallow and rapid breathing; and pale, cool, clammy skin.

Whole blood—Blood that contains red blood cells, white blood cells, and platelets in plasma.

- A crush wound may have irregular margins like a laceration; however, the wound will be deeper and trauma to muscle and bone may be apparent.
- A cut may have little or profuse bleeding depending on its depth and length; its even edges readily line up.
- A laceration may have little or profuse bleeding. The tissue damage is generally greater and the wound's ragged edges do not readily line up.
- A missile entry wound may be accompanied by an exit wound, and bleeding may be profuse, depending on the nature of the injury.
- A puncture wound will be greater in depth than in its length, therefore there is usually little bleeding around the outside of the wound and more bleeding inside, causing discoloration.

Diagnosis

A diagnosis is made by visual examination and may be confirmed by a report of the causal events. Medical personnel will also assess the extent of the wound and the effect it has had on the patient's well-being (e.g., profound blood loss, damage to the nervous system or skeletal system).

Treatment

Treatment of wounds involves stopping any bleeding, then cleaning and dressing the wound to prevent infection. Additional medical attention may be required if the effects of the wound have compromised the body's ability to function effectively.

Stopping the bleeding

Most bleeding may be stopped by direct pressure. Direct pressure is applied by placing a clean cloth or dressing over the wound and pressing the palm of the hand over the entire area. This limits local bleeding without disrupting a significant portion of the circulation. The cloth absorbs blood and allows clot formation. The clot should not be disturbed, so if blood soaks through the cloth, another cloth should be placed directly on top rather than replacing the original cloth.

If the wound is on an arm or leg that does not appear to have a broken bone, the wound should be elevated to a height above the person's heart while direct pressure is applied. Elevating the wound allows gravity to slow down the flow of blood to that area.

If severe bleeding cannot be stopped by direct pressure or with elevation, the next step is to apply pressure to the major artery supplying blood to the area of the wound. In the arm, pressure would be applied to the brachial artery by pressing the inside of the upper arm against the bone. In the leg, pressure would be applied to the femoral artery by pressing on the inner crease of the groin against the pelvic bone.

If the bleeding from an arm or leg is so extreme as to be life-threatening and if it cannot be stopped by any other means, a tourniquet may be required. However, in the process of limiting further blood loss, the tourniquet also drastically deprives the limb tissues of oxygen. As a result, the patient may live but the limb may die.

In 2004, a new solution to stopping bleeding was introduced. Called QuikClot, the U.S. Food and Drug Administration (FDA) approved substance is made up of synthetically made material called zeolite, which occurs naturally in volcanic rock. When used properly, it can be poured into a wound that will not stop

bleeding and will slow blood loss. The trauma pack costs about 50 cents and has shown particular promise in the battlefield and in wilderness situations.

Dressing the wound

Once bleeding has been stopped, cleaning and dressing the wound is important for preventing infection. Although flowing blood flushes debris from the wound, running water should also be used to rinse away dirt. Embedded particles such as wood slivers and glass splinters, if not too deep, may be removed with a needle or pair of tweezers that has been sterilized in rubbing alcohol or in the heat of a flame. Once the wound has been cleared of foreign material and washed, it should be gently blotted dry, with care not to disturb the blood clot. An antibiotic ointment may be applied. The wound should then be covered with a clean dressing and bandaged to hold the dressing in place.

Getting medical assistance

A person who has become impaled on a fixed object, such as a fence post or a stake in the ground, should be moved only by emergency medical personnel. **Foreign objects** embedded in the eye should be removed only by a doctor. Larger penetrating objects, such as a fishhook or an arrow, should be removed only by a doctor to prevent further damage as the object exits the body.

Additional medical attention is necessary in several instances. Wounds that penetrate the muscle beneath the skin should be cleaned and treated by a doctor. Such a wound may require sutures (stitches) to keep it closed during healing. Some deep wounds that do not extend to the underlying muscle may only require butterfly bandages to keep them closed during healing. Wounds to the face and neck, even small ones, should always be examined and treated by a doctor to preserve sensory function and minimize scarring. Deep wounds to the hands and wrists should be examined for nerve and tendon damage. Puncture wounds may require a **tetanus** shot to prevent serious infection. Animal bites should always be examined and the possibility of **rabies** infection determined.

Infection

Wounds that develop signs of infection should also be brought to a doctor's attention. Signs of infection are swelling, redness, tenderness, throbbing pain, localized warmth, **fever**, swollen lymph glands, the presence of pus either in the wound or draining from it, and red streaks spreading away from the wound.

Emergency treatment

With even as little as one quart of blood lost, a person may lose consciousness and go into traumatic **shock**. Because this is a life-threatening situation, emergency medical assistance should be called immediately. If the person stops breathing, artificial respiration (also called mouth-to-mouth resuscitation or rescue breathing) should be administered. In the absence of a pulse, **cardiopulmonary resuscitation** (CPR) must be performed. Once the person is breathing unassisted, the bleeding may be attended to.

In cases of severe blood loss, medical treatment may include the intravenous replacement of body fluids. This may be infusion with saline or plasma, or a **transfusion** of whole blood.

Chronic wound treatment

Treating a chronic wound involves encouraging an environment in the wound bed that promotes healing, supporting overall health and **nutrition**, and managing chronic conditions (such as diabetes) that contribute to chronic wounds. **Debridement** of dead tissue from the wound, either by surgery or with the use of enzymatic debriding medication, helps create a wound bed that enables new tissue granulation. Occlusive moist dressings encourage autolytic debridement, which is the body's own sloughing and breaking down of dead cells. Negative pressure dressings, silver-containing antimocrobial medication, **hyperbaric oxygen therapy**, **physical therapy**, and **nutritional supplements** are also available to treat chronic wounds. Chronic wounds are often chronically painful, so **pain management** is important to enable the affected person to participate fully in their care and maintain their usual activities.

In some cases, clinicians have resorted to a Civil War-era treatment that does not sound appealing, but works well enough to receive FDA approval. Maggots can be placed on wounds that refuse to heal with high–tech medical methods. The maggots are dropped into the wound and covered with special mesh to keep them in place. They are removed in two to three days.

Alternatives

In addition to the conventional treatments described above, there are alternative therapies that may help support the injured person. Homeopathy can be very effective in acute wound situations. *Ledum* (*Ledum palustre*) is recommended for puncture wounds (taken internally). Calendula (*Calendula officinalis*) is the primary homeopathic remedy for wounds. An antiseptic, it is used topically as a succus (juice), tea, or salve. Another naturally

WWW.BOOKBAZ.IR

occurring antiseptic is tea tree oil (*Melaleuca* spp.), which can be mixed with water for cleaning wounds. Aloe (*Aloe barbadensis*) can be applied topically to soothe skin during healing. When wounds affect the nerves, especially in the arms and legs, **St. John's wort** (*Hypericum perforatum*) can be helpful when taken internally or applied topically. **Acupuncture** can help support the healing process by restoring the energy flow in the meridians that have been affected by the wound. Alternative treatments should be used with care, as the benefits of many such treatments have not been confirmed by scientific research.

Prognosis

Without the complications of infection or excess blood loss, most wounds heal well with time. Depending on the depth and size of the wound, it may or may not leave a visible scar.

Generally, wounds heal in a series of progressive steps. During the inflammatory phase, which begins with the injury, blood vessels narrow and clot formation begins. Substances are also released that initiate the healing process and macrophages begin to clear the wound of debris. The next phase is one of proliferation, during which a network of collagen and new capillaries begin to form the basis of the healing wound bed. The wound appears dark pink or purple due to the presence of many new capillaries that supply blood to the healing tissue. During the phase of epithelialization, new skin cells begin to form, eventually creating a new barrier between the wound bed and outside elements. This process usually begins within about 48 hours of injury. The collagen and new skin cells become more organized during the remodeling phase, which ends in the closure of the wound with skin that is about 75% as strong as the original skin. When excess collagen is formed in a wound bed that penetrates the dermis, a scar is formed. When wound healing is severely delayed or remains in a particular phase, it becomes a chronic wound.

Prevention

Most actions that result in wounds are preventable. Injuries from motor vehicle accidents may be reduced by wearing seat belts and placing children in size-appropriate car seats in the back seat. Sharp, jagged, or pointed objects or machinery parts should be used according to the manufacturer's instructions and only for their intended purpose. Firearms and explosives should be used only by adults with explicit training; they should also be kept locked and away from children. Persons engaging in sports, games, and recreational activities should wear all proper protective equipment and follow safety rules.

Chronic wounds are best avoided by preventing the diseases that cause them. Diabetes and **peripheral vascular disease** are the major causes of chronic wounds among ambulatory people. Maintaining a healthy diet, weight, and lifestyle that includes **exercise** are helpful in preventing either of these conditions. Maintaining control of blood glucose levels, along with care of the feet and toes is important for persons with diabetes in preventing wounds that can become chronic. In non-ambulatory persons, pressure reliving devices in wheelchairs or beds, frequent changes in position, and sometimes **diets** fortified with protein, **vitamins** A and C, and the mineral zinc can help prevent chronic ulcerating wounds.

Xanthoma

Definition

Xanthoma is a skin condition in which some kinds of lipids (fats) accumulate under the skin and form yellowish-brown lumps or nodules. Xanthomas usually indicate some problem with lipid metabolism resulting in too much fat in the blood.

Description

Xanthomas, although mostly a cosmetic defect, may be a sign of a problem in fat metabolism. When too much **cholesterol** or too many lipids are in the blood, the extra material is carried to places in the body where it accumulates. The most common places are around the eyelids and over tendons or ligaments in the hands, feet, and along the Achilles tendon.

A variety of different xanthomas can develop.

- Xanthelasma palpebrarum is the most common type of xanthoma. It consists of soft, yellow, flattish bumps that develop symmetrically along the upper and lower eyelids. These start out small and enlarge over several months. Xanthelasma palpebrarum may or may not be associated with hyperlipidemia (high lipid levels).
- Tuberous xanthomas are firm, reddish, rounded, painless nodules. They form mostly on pressure points of the knees, elbows, and buttocks and are associated with high cholesterol and especially with high levels of low density lipoprotein (LDL) ("bad" cholesterol) and some inherited high-cholesterol disorders.
- Tendinous xanthomas are nodules that appear under the skin most often on tendons and ligaments of the hands and feet or along the Achilles tendon. They are associated with severely high cholesterol levels and high LDL levels.
- Eruptive xanthomas can appear anywhere on the body but are most common on the buttocks, shoulders, arms, and legs. They appear as a cluster of small bumps with a red base and a reddish-yellow top. They are associated with very high levels of triglycerides in the blood and are common in people with diabetes. These xanthomas may disappear on their own within a few weeks.
- Plane xanthomas are flat red patches that can cover a large area, often on the face, neck, or palms of the hands. They are associated with both high levels of cholesterol and high levels of triglycerides in the blood.
- Xanthoma disseminatum and verruciform xanthoma are xanthomas that occur in people with normal levels of lipids in the blood. Xanthoma disseminatum consists of many small yellowish-brown or reddish-brown bumps that appear on the face, neck, and trunk. These bumps may also appear inside the mouth. This condition gradually improves on its own, but improvement can take years. Verruciform xanthomas usually appear in the mouth as a single yellow lesion and are considered benign.

Risk factors

Having a family member with an inherited disorder in lipid metabolism increases the chance of developing a xanthoma. Xanthomas are also more common in people with diabetes, hyperlipidemia, certain types of liver **cirrhosis**, **pancreatitis**, and **hypothyroidism** (low thyroid hormone levels).

Demographics

Xanthomas are common in individuals with lipid metabolism disorders, although no exact numbers are available. They occur equally in men and women and are most likely to occur in individuals over age 50 years.

WWW.BOOKBAZ.IR

Skin nodules on the elbows and arms of a person with xanthoma. *(O.J. Staats MD Custom Medical Stock Photo/Newscom)*

Causes and Symptoms

Xanthomas are caused by too many lipids in the blood. The elevated lipid levels can be caused by an inherited error in lipid metabolism such as familial **hypercholesterolemia** or hyperlipoprotenaemia or by any of the diseases listed under risk factors. Some types of xanthomas are unrelated to high lipid levels. The appearance of xanthomas varies with their type and cause as described above.

Even though xanthomas are primarily a cosmetic problem, they usually signal some underlying disease or disorder that needs to be diagnosed and treated because high cholesterol levels and high triglyceride levels increase the chance of developing **coronary artery disease**, arteriosclerosis, **heart attack**, and **stroke**.

Diagnosis

Diagnosis initially involves blood and urine tests. These usually are followed by additional testing to locate the underlying cause of the disease.

Treatment

Xanthomas are treated by treating or managing the underlying disease. This may involve the use of cholesterol-lowering drugs such as statins to reduce the likelihood of heart attack and stroke.

Alternatives

Changes in diet to reduce the intake of foods high in fat and cholesterol is especially important in treating xanthomas and improving heart health. **Exercise** may also help reduce the levels of lipids in the blood. In people with xanthomas, these changes usually must be accompanied by lipid-lowering drugs.

Prognosis

Xanthomas by themselves do not cause health problems, but they are a sign of serious problems that can compromise heart health and increase the risk of death by stroke or heart attack. Keeping blood lipid levels under control helps to reduce this risk.

Prevention

Inherited diseases that cause errors in lipid metabolism cannot be prevented. A healthy diet, regular exercise, and maintaining a normal weight can prevent some of the diseases such as type 2 diabetes that may be associated with xanthomas.

Xerostomia *see* **Dry mouth**

XLA *see* **X-linked agammaglobulinemia**

X-linked agammaglobulinemia

Definition

X-linked agammaglobulinemia (XLA), or Bruton's agammaglobulinemia, is present at birth (congenital) and is characterized by low or completely absent levels of immunoglobulins in the bloodstream. Immunoglobulins are protein molecules in blood serum that function like antibodies. Without them, the body lacks a fully functioning immune system. Persons with XLA are vulnerable to repeated, potentially fatal bacterial infections.

Description

XLA occurs in one in 50,000 to one in 100,000 newborns. Almost all persons with the disorder are males. Although persons with XLA carry the genes to produce immunoglobulins, a genetic defect on the X chromosome prevents their formation. This defect is not associated with the immunoglobulins themselves, but rather with the B cells in the bloodstream that ordinarily secrete the immunoglobulins.

B cells are a type of white blood cell. They are the sole producers of immunoglobulins in the body. B cells are produced in the bone marrow and carried to the spleen, lymph nodes, and other organs as they mature. The maturation process depends on an enzyme called Bruton's agammaglobulinemia tyrosine kinase (Btk). If Btk is missing or defective, the B cells cannot mature and cannot produce immunoglobulins.

The gene for Btk is on the X chromosome. Certain changes (mutations) in this gene result in defective Btk. Since the gene is carried on the X chromosome, XLA individuals are almost always male. Females have two X chromosomes, which means they have two copies of the Btk gene, one of which is normal. Males have only one X chromosome.

Causes and symptoms

XLA is caused by a defect in the gene that codes for Btk. This defect leads to blocked maturation of B cells, the cells that produce immunoglobulins. Because other portions of the immune system are functional, people with XLA can fight off some types of infection, such as fungal and most viral infections. Immunoglobulins, however, are vital to combat bacterial infections. Infants with XLA usually do not show symptoms during the first six months of life because immunoglobulins from their mothers are circulating in their bloodstreams. As the mother's supply decreases, the baby becomes increasingly vulnerable to bacterial infections.

Common symptoms of immunoglobulin deficiency appear after the infant is six months old. They include frequent ear and sinus infections, **pneumonia**, and **gastroenteritis**. Certain viruses, such as hepatitis and **polio**, can also pose a threat. Children with XLA grow slowly, have small tonsils and lymph nodes, and may develop chronic skin infections. Approximately 20% of these children develop arthritis, possibly as a result of joint infections.

Diagnosis

Frequent bacterial infections, a lack of mature B cells, and low-to-nonexistent levels of immunoglobulins point to a diagnosis of XLA. A sample of the infant's blood serum can be analyzed for the presence of immunoglobulins by a technique called **immunoelectrophoresis**. To make a definitive diagnosis, the child's

WWW.BOOKBAZ.IR

KEY TERMS

Antibody—A molecule that is produced by the immune system in response to a protein, called an antigen, that is not recognized as belonging in the body.

B cell—A type of lymphocyte, or white blood cell, that is a key component of the body's immune system. Mature B cells produce immunoglobulins.

Bruton's agammaglobulinemia tyrosine kinase (Btk)—An enzyme vital for the maturation of B cells.

Carrier—A person who has a genetic defect but does not develop any symptoms or signs of the defect. The carrier's offspring may inherit the defect and develop the associated disorder.

Enzyme—A protein molecule that prompts rapid biochemical reactions.

Immunoglobulin—A protein molecule formed by mature B cells in response to foreign proteins in the body. There are five types of immunoglobulins, but the major one is gamma globulin, or immunoglobulin G.

Mutation—A change in a gene that alters the function or other characteristics of the gene's product.

X chromosome—One of the two sex chromosomes (the other is Y) that determine a person's gender. Normal males have both an X and a Y chromosome, and normal females have two X chromosomes.

X chromosome is analyzed for defects in the Btk gene. Similar analysis can be used for prenatal diagnosis or to detect carriers of the defective gene.

Treatment

Treatment of XLA consists of regular intravenous doses of commercially prepared **gamma globulin** (sold under the trade names Gamimune or Gammagard) to ward off infections. **Antibiotics** are used to treat infections as they occur. Children with XLA must be treated promptly for even minor cuts and scrapes and taught to avoid crowds and people with active infections.

Prognosis

Prior to the era of gamma globulin and antibiotic treatment, approximately 90% of XLA individuals died before age 8. Early diagnosis and current therapy allows most individuals with XLA to reach adulthood and lead relatively normal lives. Infants who develop polio or persistent viral infections, however, have a poorer prognosis.

Prevention

Parents of a child with XLA should consider **genetic counseling** if they are planning to have more children.

Y

Yaws

Definition

Yaws is a chronic illness that first affects the skin and then affects the bones.

Description

Yaws tends to strike children, particularly between the ages of two and five. It is common in areas where poverty and overcrowding interfere with good hygiene practices. The most common locations are in rural areas throughout Africa, Southeast Asia, and in locations bordering the equator in the Americas.

Causes and symptoms

Yaws is caused by a spiral-shaped bacterium (spirochete) called *Treponema pertenue*. This bacterium belongs to the same family as the bacterium that causes **syphilis**.

Yaws is passed among people by direct skin contact. It requires some kind of a scratched or insect bitten area in order for the bacteria to actually settle in and cause infection. An injured spot on the leg is the most common part of the body through which the bacteria enter. Young children, who are constantly bumping themselves in play, who wear little clothing, who do not wash their hands often, and who may frequently put their hands in their mouths, are particularly susceptible.

The first symptom of yaws occurs three to four weeks after acquiring the bacteria. The area where the bacteria originally entered the skin becomes a noticeable bump (papule). The papule grows larger and develops a punched-out center (ulcer), covered with a yellow crust. Lymph nodes in the area may become swollen and tender. This first papule may take as long as six months to heal. Secondary soft, gummy growths then appear on the face, arms and legs, and buttocks. These soft, tumor-like masses may grow on the soles of the feet, causing the patient to walk in an odd and characteristic fashion on the sides of his or her feet (nicknamed "crab yaws"). More destructive tumors may then disrupt the bones of the face, the jaw, and the lower leg. **Ulcers** around the nose and on the face may be very mutilating.

Diagnosis

Samples taken from the first papules may be examined using a technique called dark-field microscopy. This often allows the spirochetes to be identified. They may also be identified in fluid withdrawn from swollen lymph nodes. Various tests can also be run on blood samples to determine if an individual is producing antibodies (special immune cells) which are specifically made in response to the presence of these spirochetes.

Treatment

A single penicillin injection in a muscle is sufficient to completely end the disease.

Prognosis

Without treatment, yaws is a terribly disfiguring, chronic illness. With appropriate treatment, the progression of the disease can be completely halted.

Prevention

For a time, the World Health Organization (WHO) was working to totally eradicate yaws, just as **smallpox** was successfully eradicated. This has not occurred, however. WHO continues to work to identify and respond to outbreaks quickly, in an effort to at least slow the spread of yaws.

Yellow fever

Definition

Yellow **fever**, also known as sylvatic fever and viral hemorrhagic fever or VHF, is a severe **infectious disease** caused by a type of virus called a flavivirus. This flavivirus can cause outbreaks of epidemic proportions throughout Africa and tropical America.

Demographics

Yellow fever is found most commonly in men between the ages of 15 and 45 years who work outdoors and live in fever-endemic areas. Race has not been shown to be a factor in contraction or transmission. The World Health Organization reports there are about 200,000 new cases annually that result in approximately 30,000 deaths worldwide. Between 1970 and 2002, only nine cases of yellow fever were reported in travelers from the United States and Europe. All cases were found in unimmunized travelers who had visited South America or Africa. Seven of the cases were fatal.

Description

The first written evidence of a yellow fever epidemic occurred in the Yucatan in 1648. Since that time, much has been learned about the interesting transmission patterns of this devastating illness. It is thought that the disease originated in Africa and spread to the Americas in the seventeenth and eighteenth centuries through trading ships. The flavivirus that causes yellow fever was first identified in 1928 and the first vaccine against the disease was produced at the Rockefeller Institute in New York in 1937.

In order to understand how yellow fever is passed, several terms need to be defined. The word "host" refers to an animal that can be infected with a particular disease. The term "vector" refers to an organism that can carry a particular disease-causing agent (such as a virus or bacteria) without actually developing the disease. The vector can then pass the virus or bacterium on to a new host.

Many of the common illnesses in the United States (including the **common cold**, many viral causes of **diarrhea**, and **influenza** or "flu") are spread by direct passage of the causative virus between human beings. Yellow fever, however, cannot be passed directly from one infected human to another. Instead, the virus responsible for yellow fever requires an intermediate vector, a mosquito, which carries the virus from one host to another.

The hosts of yellow fever include both humans and monkeys. The cycle of yellow fever transmission occurs as follows: an infected monkey is bitten by a tree-hole breeding mosquito. This mosquito acquires the virus and can pass the virus on to any number of other monkeys that it may bite. This form of yellow fever is known as sylvatic yellow fever, and usually affects humans only incidentally. When a human is bitten by an infected mosquito, the human may acquire the virus. In the case of South American yellow fever, the infected human may return to the city, where an urban mosquito (*Aedes aegypti*) serves as a viral vector, spreading the infection rapidly by biting humans. This form of the disease is known as urban yellow fever or epidemic yellow fever.

Yellow fever epidemics also may occur after flooding caused by earthquakes and other natural disasters. They result from a combination of new habitats available for the vectors of the disease and changes in human behavior (spending more time outdoors and neglecting sanitation precautions).

Cases of yellow fever are uncommon in the United States and Canada as of 2015. The last reported case of a U.S. citizen dying of yellow fever concerned a man who contracted yellow fever after visiting Venezuela in 1999. The man had not been vaccinated against yellow fever. The last epidemic in the United States occurred in New Orleans in 1905.

Causes and symptoms

Once a mosquito has passed the yellow fever virus to a human, the chance of disease developing is about 5%–20%. Infection may be fought off by the host's immune system or may be so mild that it is never identified.

WILBUR AUGUSTUS SAWYER (1879–1951)

Wilbur Augustus Sawyer was born in Appleton, Wisconsin, on August 7, 1879, to Minnie Edmea (Birge) and Wesley Caleb Sawyer. The Sawyers moved to Oshkosh, Wisconsin, and finally to Stockton, California, in 1888. Sawyer spent two years at the University of California and then entered Harvard College where he earned his A.B. degree in 1902. In 1906, Sawyer graduated from Harvard Medical School and began a private practice, which lasted until he started his internship at Massachusetts General Hospital. Sawyer returned to California in 1908 in order to obtain a position at the University of California as a medical examiner. He then worked with the California State Board of Health from 1910 until 1918. In 1911, Sawyer married Margaret Henderson. The couple had three children.

Sawyer's first publication (1913) dealt with his research of poliomyelitis. His discovery, in 1915, that examination of the individual's stool could lead to detection of the disease was later regarded as very significant. In 1918 and 1919, Sawyer worked to control venereal disease while employed by the Army Medical Corps. In 1926 and 1927, while director of the West African Yellow Fever Commission, Sawyer succeeded in isolating the yellow fever virus. He would ultimately return to the United States, where he and Wray Lloyd would devise an immunization against yellow fever (1931).

In 1944, Sawyer became director of health for the United Nations Relief and Rehabilitation Administration, a position he held for three years. He retired to Berkeley, California, where he died on November 12, 1951. The company he built with his brother still thrives today.

In human hosts who develop the disease yellow fever, there are five distinct stages through which the infection evolves. These have been termed the periods of incubation, invasion, remission, intoxication, and convalescence.

Yellow fever's incubation period (the amount of time between the introduction of the virus into the host and the development of symptoms) is three to six days. During this time, there are generally no symptoms identifiable to the host.

The period of invasion lasts two to five days, and begins with an abrupt onset of symptoms, including fever and chills, intense **headache** and lower backache, muscle aches, nausea, and extreme exhaustion. The patient's tongue shows a characteristic white, furry coating in the center, surrounded by a swollen, reddened margin. While most other infections that cause a high fever also cause an increased heart rate, yellow fever results in an unusual finding, called Faget's sign. This is the simultaneous occurrence of a high fever with a slowed heart rate. Throughout the period of invasion, there are still live viruses circulating in the patient's bloodstream. Therefore, a mosquito can bite the ill patient, acquire the virus, and continue passing it on to others.

The next phase is the period of remission. The fever falls, and symptoms decrease in severity for several hours to several days. In some patients, this signals the end of the disease; in other patients, this proves only to be the calm before the storm.

The period of intoxication represents the most severe and potentially fatal phase of the illness. During this time, lasting three to nine days, a type of degeneration of the internal organs (specifically the kidneys, liver, and heart) occurs. This fatty degeneration results in what is considered the classic triad of yellow fever symptoms: **jaundice**, black vomit, and the dumping of protein into the urine. Jaundice causes the whites of the patient's eyes and the patient's skin to take on a distinctive yellow color. This is due to liver damage, and the accumulation of a substance called bilirubin, which is normally processed by a healthy liver. The liver damage also results in a tendency toward bleeding; the patient's vomit appears black due to the presence of blood. Protein, which is normally kept out of the urine by healthy, intact kidneys, appears in the urine due to disruption of the kidney's healthy functioning.

Patients who survive the period of intoxication enter into a relatively short period of convalescence. They recover with no long-term effects related to the yellow fever infection. Infection with the yellow fever virus results in lifelong immunity against repeated infection with the virus.

The course of yellow fever is complicated in some patients by secondary bacterial infections.

Diagnosis

Examination

A diagnosis of yellow fever may be suspected during a physical exam when the classic triad of symptoms are present. These include:

- a sudden onset of fever, chills, intense headaches and lower backaches, muscle aches, nausea, and exhaustion
- Faget's sign—simultaneous occurance of a high fever and increased heart rate
- a white furry coating in the center of the tongue surround by a swollen, red margin

WWW.BOOKBAZ.IR

KEY TERMS

Antibody—A protein normally produced by the immune system to fight infection or rid the body of foreign material. The material that stimulates the production of antibodies is called an antigen. Specific antibodies are produced in response to each different antigen and can only inactivate that particular antigen.

Antigen—Any foreign substance, usually a protein, that stimulates the body's immune system to produce antibodies.

Bilirubin—A reddish-yellow bile pigment made by the liver.

Dialysis—The cleansing of the blood through use of a special machine that filters the blood. Dialysis is done when the kidneys are unable to filter blood properly.

Epidemic—A situation in which a particular disease spreads rapidly through a population of people.

Faget's sign—The simultaneous occurrence of a high fever with a slowed heart rate.

Flavivirus—The virus that causes yellow fever.

Hemorrhage—Abnormal and obsessive bleeding.

Host—The organism (such as a monkey or human) in which another organism (such as a virus or bacteria) is living.

Jaundice—The yellowing of the skin and whites of the eyes caused by an increased level of bilirubin in the blood.

Sylvatic—Pertaining to or living in the woods or forested areas. The form of yellow fever transmitted by mosquitoes to rainforest monkeys is called sylvatic yellow fever.

Vector—A carrier organism (such as a fly or mosquito) that serves to deliver a virus (or other agent of infection) to a host.

Tests

Diagnosis of yellow fever depends on the examination of blood by various techniques in order to demonstrate either yellow fever viral antigens (the part of the virus that stimulates the patient's immune system to respond) or specific antibodies (specific cells produced by the patient's immune system that are directed against the yellow fever virus). The most rapid method of diagnosis as of 2014 was capture enzyme immunoassay.

Procedures

Typically, the only procedure required for diagnosis is a blood draw so that the blood can be evaluated for signs of yellow fever.

Treatment

As of 2014, the only treatments for yellow fever were given to relieve its symptoms. Fevers and **pain** should be relieved with **acetaminophen**, not **aspirin** or ibuprofen, both of which could increase the already-present risk of bleeding. **Dehydration** (due to fluid loss both from fever and bleeding) needs to be carefully avoided. This can be accomplished by increasing fluids. The risk of bleeding into the stomach can be decreased through the administration of **antacids** and other medications. Hemorrhage (heavy bleeding) may require blood transfusions. Kidney failure may require dialysis (a process that allows the work of the kidneys in clearing the blood of potentially toxic substances to be taken over by a machine, outside of the body).

Drugs

There were no antiviral treatments available as of 2014 to combat the yellow fever virus. Nonclinical research has led to limited results.

Researchers have found that ribavirin (Virazole, Rebetol), a drug that is given by mouth to treat **hepatitis C**, is successful in reducing mortality from yellow fever in hamsters, but only if given within 120 hours of infection. Another drug, Interferon-alpha has also been found to reduce mortality in monkeys with yellow fever but only when administered within 24 hours of infection.

Prognosis

Five to ten percent of all diagnosed cases of yellow fever are fatal. Jaundice occurring during a yellow fever infection is an extremely grave predictor; 20-50% of these patients die of the infection. Death may occur due to massive bleeding (hemorrhage), often following a lapse into a comatose (unconscious) state.

Prevention

A very safe and very effective yellow fever vaccine exists. The Arilvax vaccine is made from a live attenuated (weakened) form of the yellow fever virus, strain 17D. In the United States, the vaccine is given only at Yellow Fever **Vaccination** Centers authorized by the United States **Public Health** Service. About 95% of vaccine recipients acquire long-term immunity to the yellow fever virus. Careful measures to decrease

mosquito populations in both urban areas and jungle areas where humans are working, along with programs to vaccinate all people living in such areas, are necessary to avoid massive yellow fever outbreaks.

Individuals planning to travel to countries where yellow fever is endemic may obtain up-to-date information on yellow fever vaccination from the Centers for Disease Control and Prevention.

Yersinia enterocolitica infection
see **Yersinosis**

Yersinia pestis see **Plague**

Yersinia pseudotuberculosis infection
see **Yersinosis**

Yersinosis

Definition

Yersinosis refers to infection by a genus of bacteria known as *Yersinia*. The two sub-types that are responsible for yersinosis are *Yersinia enterocolitica* and *Yersinia pseudotuberculosis*. The diseases produced by these organisms are called "zoonoses," because the bacteria is passed to humans from animal sources.

The name *Yersinia* comes from Dr. Alexandre Yersin, who was the first person to grow a much more deadly type of *Yersinia* known as *Yersinia pestis*, the bacteria responsible for what is now known as bubonic **plague**. The subject of this entry is the more common forms of *Yersinia*, namely *Y. enterocolitica* and *Y. pseudotuberculosis*.

Description

Yersinia are classified as gram-negative bacteria (bacteria that do not accept the color of a stain in a Gram stain test, which indicates the general chemical nature of the cell wall of the bacteria); they have a variety of appearances and are therefore called pleomorphic. They belong to Enterobacteriacae, the large group of organisms that inhabit the intestinal tract. There are many different subtypes of *Yersinia*.

They are found worldwide and have been isolated from soil, fresh water, contaminated foods, and many wild and domestic animals. For reasons not entirely clear, disease caused by these organisms occurs more frequently in areas of northern Europe, especially Scandinavia. Infection, particularly in children ages one through four years, is quite common, though often these infections produce few symptoms. Studies have shown that infection with these bacteria is almost as common as that with *Shigella* or *Campylobacter*.

Causes and symptoms

Animals are the most important sources of bacterial infection for humans. Whether from pets or undercooked meat (especially pork), these bacteria almost always enter the human body through the mouth (oral

WWW.BOOKBAZ.IR

transmission). An incubation period of one to eleven days passes before signs of disease develop. Rare cases have been transmitted by way of contaminated blood transfusions.

Yersinia produces several different types of disease. The most common form is a short-lived inflammation of the intestine known as enterocolitis. Most often the very end of the small intestine is involved, an area known as the terminal ileum. The result is **gastroenteritis**, with cramping abdominal **pain**, **fever**, and **diarrhea**. Diarrhea generally continues for two weeks or so, but can go on for many months. Up to 40% of patients also experience **nausea and vomiting**, and in one-third, inflammation of the intestine leads to bleeding.

In other patients, the same area of the intestine is involved, but instead of causing diarrhea, a syndrome resembling **appendicitis** occurs. In this syndrome, the lymph nodes surrounding the intestine are especially involved; this has lead to the term mesenteric adenitis. Although this syndrome resolves without serious consequences, it is often difficult to differentiate from appendicitis, and leads to surgery in some instances. **Ultrasound** exam may be able to demonstrate a normal appendix and avoid surgery. Why some patients develop symptoms of gastroenteritis, and others only inflammation, pain, and fever, is unknown.

In some patients, *Yersinia* produces infection of areas other than the intestinal tract. These include:

- Inflammation of the throat (pharyngitis) and tonsillitis; this can be quite severe and even lead to death, particularly in adults.
- Septicemia, or infection of the blood stream, with spreading of infection to other organs such as bone, meninges, kidneys, and others. Individuals with decreased immunity due to liver disease, diabetes, cancer, and other diseases are at increased risk for this complication.

Different parts of the body may be affected (such as joints, eyes, and urinary system) by changes in the immune system caused by *Yersinia* infection. Arthritis, which is especially frequent in Scandinavia, occurs in up to 10% of *Yersinia* infections. About one week after typical intestinal symptoms, swelling and pain in multiple joints occurs. The knees and ankles are most often involved and become inflamed over a period of two weeks. In two-thirds of those affected, symptoms gradually resolve over one to three months without need for treatment. Rarely does chronic joint disease develop.

Inflammation of the heart muscle, called **myocarditis**, sometimes occurs together with the arthritis. In about 15%–20% of patients, the skin develops a red, raised area, usually located on the shins, called **erythema nodosum**. This appears within a few weeks of the intestinal symptoms and disappears over a month or so.

KEY TERMS

Mesenteric adenitis—Inflammation of the lymph nodes that serve the small intestine, with symptoms similar to appendicitis.

Septicemia—Systemic disease associated with the presence of microorganisms or their toxins in the blood; blood poisoning.

Diagnosis

Identifying *Yersinia* as the cause of all or any of these symptoms is not an easy task. It is possible to grow the organism from stool cultures, but this is difficult to do unless special methods are used.

A change in antibody levels can also be used to determine the presence of infection. To be accurate, levels must be initially examined early in the illness. Therefore, it is most important for the possible diagnosis and examination to be thought of early.

Treatment

Since most of the symptoms caused by *Yersinia* are self limiting, specific antibiotic treatment is generally not needed. Patients with **dehydration** from gastroenteritis are given supportive therapy, including treatment aimed at replacing fluids.

Antibiotics are indicated, however, for those patients who develop more severe infections, such as invasion of the bloodstream (septicemia), or who develop infections at specific sites, such as bone. A variety of antibiotics have been used, but it is not clear which produces the best results.

No specific treatment is indicated for the joint, ocular, skin, or urinary symptoms that result from infection. As stated, these are not due to direct invasion by the bacteria, but are related to changes in immune reactions produced by the infection. However, treatment of those experiencing severe arthritic symptoms with NSAIDS (**nonsteroidal anti-inflammatory drugs**) or steroid injection at inflamed joints is used in selected cases.

Prognosis

As noted, most of the time, *Yersinia* infection has an excellent outlook. However, when these bacteria

invade the bloodstream or produce disease beyond the gastrointestinal tract, the outlook is less positive. This may be because more severe infections occur in those with decreased immunity. The death rate from septicemia has been reported to be as high as 50%.

Prevention

Safe food handling procedures and food-preparation practices are by far the best means of avoiding infection. Undercooked food, especially pork or other animal products, should not be eaten.

Yoga

Definition

The term *yoga* comes from a Sanskrit word which means yoke or union. Traditionally, yoga is a method for joining the individual self with the Divine, Universal Spirit, or Cosmic Consciousness. Physical and mental exercises are designed to help achieve this goal, also called self-transcendence or enlightenment. On the physical level, yoga postures, called *asanas*, are designed to tone, strengthen, and align the body. These postures are performed to make the spine supple and healthy and to promote blood flow to all the organs, glands, and tissues, keeping all the bodily systems healthy. On the mental level, yoga uses breathing techniques (*pranayama*) and **meditation** (*dyana*) to quiet, clarify, and discipline the mind. However, experts are quick to point out that yoga is not a religion, but a way of living with health and peace of mind as its aims.

Purpose

Yoga has been used to alleviate problems associated with high blood pressure, high **cholesterol**, migraine headaches, **asthma**, shallow breathing, backaches, **constipation**, diabetes, **menopause**, **multiple sclerosis**, **varicose veins**, **carpal tunnel syndrome**, and many chronic illnesses. It also has been studied and approved for its ability to promote relaxation and reduce **stress**.

Yoga is increasingly recommended for **dysmenorrhea**, **premenstrual syndrome**, and other disorders in premenopausal women in Europe as well as in the United States.

Yoga can also provide the same benefits as any well-designed **exercise** program, increasing general health and stamina, reducing stress, and improving those conditions brought about by sedentary lifestyles. Yoga has the added advantage of being a low-impact activity that uses only gravity as resistance, which makes it an excellent **physical therapy** routine; certain yoga postures can be safely used to strengthen and balance all parts of the body. A study published in

Yoga positions

Name	Description
Boat	Sitting on floor with knees bent, extend legs out at a 45-degree angle to the floor so that body forms a "V" shape. Arms should be parallel to the ground.
Bridge	Lying on back with knees bent and feet flat on floor, raise pelvis off floor and arch back, keeping shoulders pressed to the ground.
Camel	While kneeling, arch back and bend head back toward feet. Hold heels with hands and exhale while in movement.
Cat-cow	On hands and knees, arch back and inhale, looking at ceiling. On exhale, round back and drop head down.
Child	Kneeling with arms to the side, roll torso to floor and rest forehead on the ground.
Cobra	Stretched out on floor with stomach down, align elbows beneath shoulders and raise torso up. Arms should straighten with hands flat on floor.
Corpse	Lie on back with feet and arms outstretched. Breathe deeply.
Downward Dog	From hands and knees, form an inverted "V" by straightening legs and pressing hands and heels to floor. Exhale while in movement.
Locust	Lying on stomach with hands at sides, squeeze buttocks and lift legs up off the ground. Simultaneously lift head, chest, and arms.
Mountain	Standing with feet together, inhale while raising arms straight above the head and clasp hands together. Exhale while lowering arms.
Spinal twist	Sitting with right foot crossed over left leg, grasp right leg with left arm and twist to the right. Repeat on other side.
Tree	While standing, place one foot on the inside of the opposite thigh. Place hands in prayer position in front of chest, and then extend toward ceiling.
Triangle	Standing with legs slightly wider than hip width, turn one foot out and reach for that foot, extending opposite arm toward ceiling.
Warrior I	Raise arms over head with palms together and lunge forward with one foot, keeping thigh parallel to the ground.
Warrior II	From Warrior I, rotate back foot so that it is perpendicular with front heel and extend arms straight out to sides. Look out over front hand.

Yoga is a system that benefits the body, mind, and spirit by teaching self-control through a series of postures and exercises as well as through breathing, relaxation, and meditation techniques. *(Illustration by Electronic Illustrators Group. © Cengage Learning®.)*

late 2002 summarized findings about the benefits of yoga for the cardiovascular and musculoskeletal systems. The review noted that yoga is still viewed as a "trendy" form of exercise rather than one with documented medical benefits.

Meditation has been much studied and approved for its benefits in reducing stress-related conditions. The landmark book *The Relaxation Response*, by Harvard cardiologist Herbert Benson, showed that meditation and breathing techniques for relaxation could have the opposite effect of stress, reducing blood pressure and other indicators. Since then, much research has reiterated the benefits of meditation for **stress reduction** and general health. The American Medical Association recommends meditation techniques as a first step before medication for borderline **hypertension** cases. Some 2002 studies indicated that yogic meditation by itself is effective in lowering serum cholesterol as well as blood pressure.

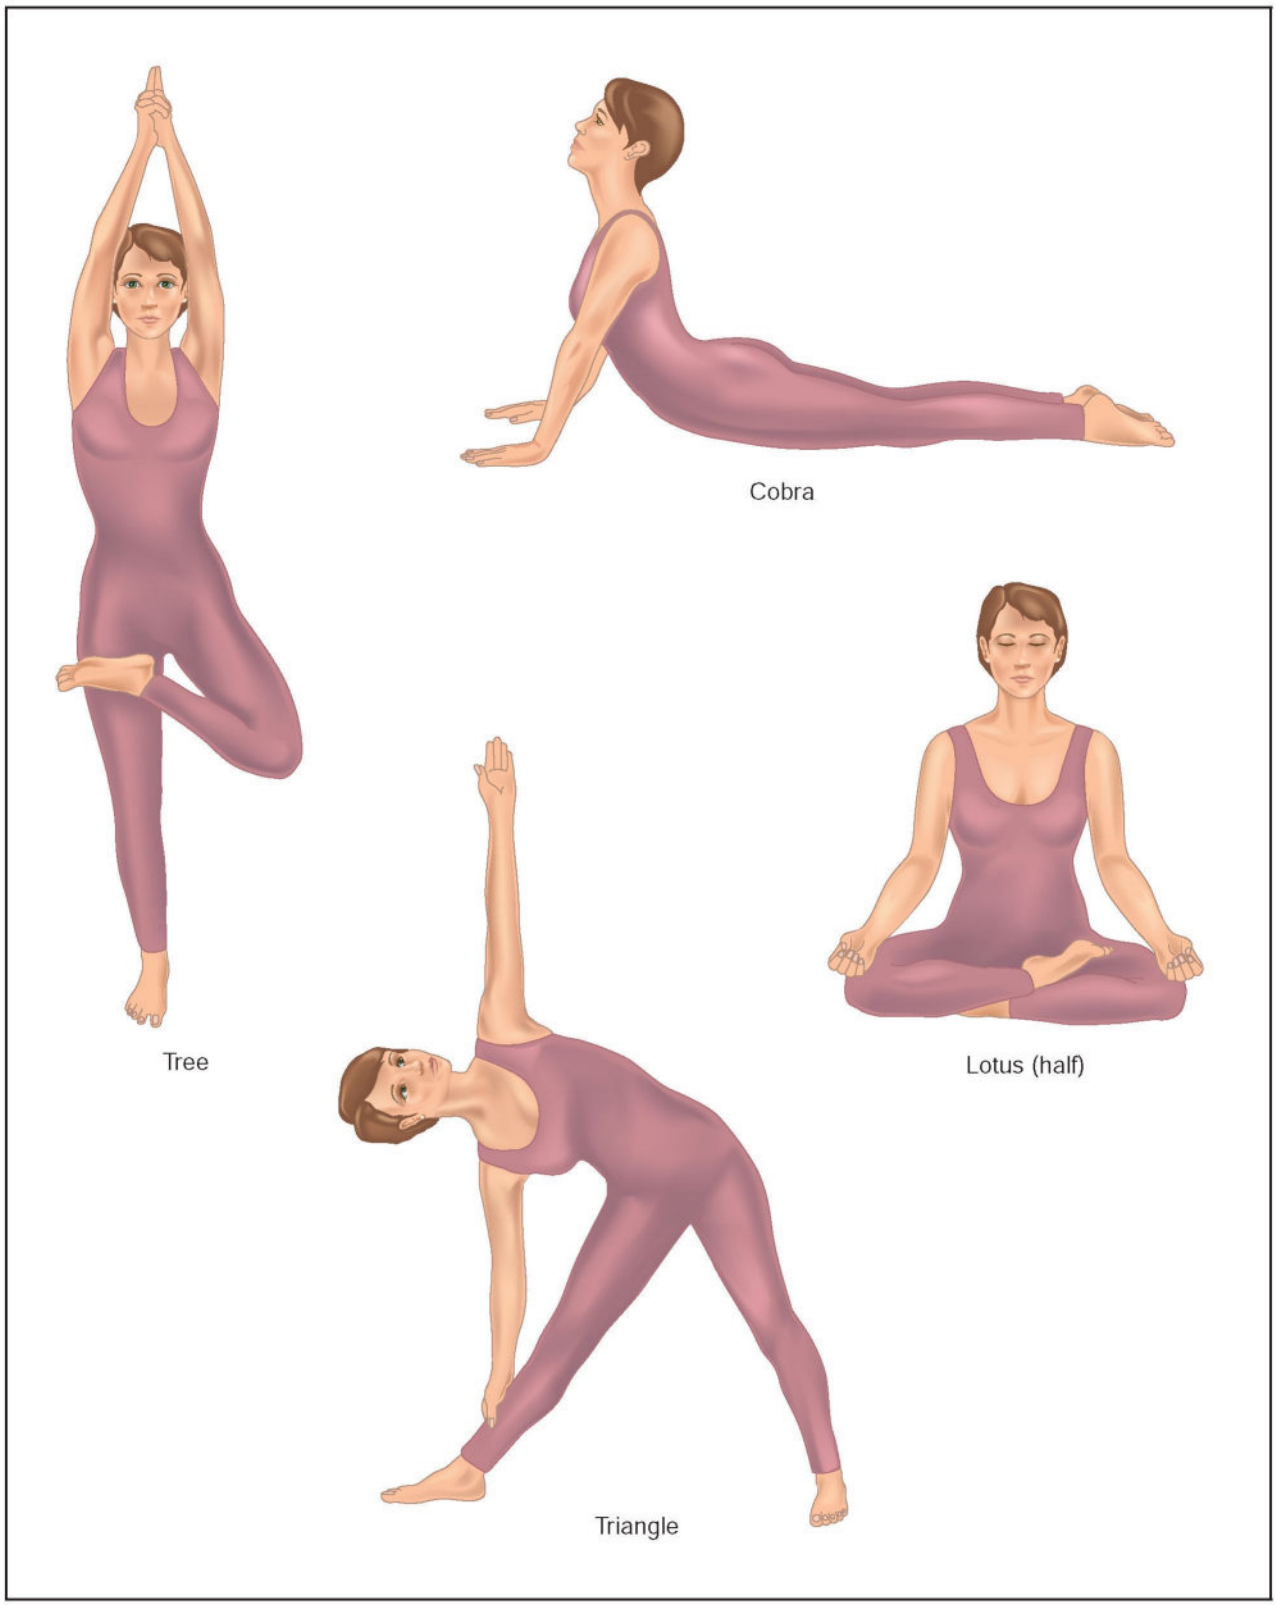
Modern psychological studies have shown that even slight facial expressions can cause changes in the involuntary nervous system; yoga utilizes the mind/body connection. That is, yoga practice contains the central ideas that physical posture and alignment can influence a person's mood and self-esteem, and also that the mind can be used to shape and heal the body. Yoga practitioners claim that the strengthening of mind/body awareness can bring eventual improvements in all facets of a person's life.

Description

Origins

Yoga originated in ancient India and is one of the longest surviving philosophical systems in the world. Some scholars have estimated that yoga is as old as 5,000 years; artifacts detailing yoga postures have been found in India from over 3000 B.C. Yoga masters (*yogis*) claim that it is a highly developed science of healthy living that has been tested and perfected for all these years. Yoga was first brought to the United States in the late 1800s when Swami Vivekananda, an Indian teacher and yogi, presented a lecture on meditation in Chicago. Yoga slowly began gaining followers and flourished during the 1960s when there was a surge of interest in Eastern philosophy. There has since been a vast exchange of yoga knowledge in the United States, with many students going to India to study and many Indian experts coming here to teach, resulting in the establishment of a wide variety schools. Today, yoga is thriving, and it has become easy to find teachers and practitioners throughout the United States. One Roper poll, commissioned by *Yoga Journal*, found that 11 million Americans do yoga at least occasionally and 6 million perform it regularly. Yoga stretches are used by physical therapists and professional sports teams, and the benefits of yoga are being touted by movie stars and *Fortune* 500 executives. Many prestigious schools of medicine have studied and introduced yoga techniques as proven therapies for illness and stress. Some medical schools, such as UCLA, even offer yoga classes as part of their physician training program.

Classical yoga is separated into eight limbs, each a part of the complete system for mental, physical and spiritual well-being. Four of the limbs deal with mental and physical exercises designed to bring the mind in tune with the body. The other four deal with different stages of meditation. There are six major types of yoga, all with the same goals of health and harmony but with varying techniques: hatha, raja, karma, bhakti, jnana, and tantra yoga. **Hatha yoga** is the most commonly



Demonstrations of the tree, triangle, cobra, and lotus poses. The tree and triangle are good for balance and coordination. Cobra stretches the pelvic and strengthens the back. Lotus is a meditative pose. *(Illustration by Electronic Illustrators Group. © Cengage Learning®.)*

WWW.BOOKBAZ.IR

PATANJALI (SECOND CENTURY B.C.)

There is little historical information available on Patanjali, who is credited with developing yoga, one of the six systems of Hindu philosophy. Several scholars suggest several persons may have developed yoga under the pseudonym of Patanjali. In any case, Patanjali existed around 150 B.C. in India. He developed yoga based on a loose set of doctrines and practices from the Upanishads, themselves a set of mystical writings. The Upanishads are part of the Aranyakas, philosophical concepts that are part of the Veda, the most ancient body of literature of Hinduism. Patanjali gave these combined philosophical and esoteric writings a common foundation in his *Yoga Sutra*, a set of 196 concise aphorisms (wise sayings) that form the principles of yoga. He also drew upon Samkhya, the oldest classic system of Hindu philosophy. Patanjali's yoga accepted Samkhya metaphysics and the concept of a supreme soul. He established an eight-stage discipline of self-control and meditation. The individual sutras (verses) lay out the entire tradition of meditation. They also describe the moral and physical disciplines needed for the soul to attain absolute freedom from the body and self.

practiced branch of yoga in the United States, and it is a highly developed system of nearly 200 physical postures, movements and breathing techniques designed to tune the body to its optimal health. The yoga philosophy believes the breath to be the most important facet of health, as the breath is the largest source of *prana*, or life force, and hatha yoga utilizes *pranayama*, which literally means the science or control of breathing. Hatha yoga was originally developed as a system to make the body strong and healthy enough to enable mental awareness and spiritual enlightenment.

There are several different schools of hatha yoga in the United States; the two most prevalent ones are Iyengar and ashtanga yoga. Iyengar yoga was founded by B.K.S. Iyengar, who is widely considered as one of the great living innovators of yoga. Iyengar yoga puts strict emphasis on form and alignment, and uses traditional hatha yoga techniques in new manners and sequences. Iyengar yoga can be good for physical therapy because it allows the use of props like straps and blocks to make it easier for some people to get into the yoga postures. Ashtanga yoga can be a more vigorous routine, using a flowing and dance-like sequence of hatha postures to generate body heat, which purifies the body through sweating and deep breathing.

The other types of yoga show some of the remaining ideas which permeate yoga. Raja yoga strives to bring about mental clarity and discipline through meditation, simplicity, and non-attachment to worldly things and desires. Karma yoga emphasizes charity, service to others, non-aggression, and non-harming as means to awareness and peace. Bhakti yoga is the path of devotion and love of God, or Universal Spirit. Jnana yoga is the practice and development of knowledge and wisdom. Finally, tantra yoga is the path of self-awareness through religious rituals, including awareness of sexuality as sacred and vital.

A typical hatha yoga routine consists of a sequence of physical poses, or asanas, and the sequence is designed to work all parts of the body, with particular emphasis on making the spine supple and healthy and increasing circulation. Hatha yoga asanas utilize three basic movements: forward bends, backward bends, and twisting motions. Each asana is named for a common thing it resembles, like the sun salutation, cobra, locust, plough, bow, eagle, tree, and the head to knee pose, to name a few. Each pose has steps for entering and exiting it, and each posture requires proper form and alignment. A pose is held for some time, depending on its level of difficulty and one's strength and stamina, and the practitioner is also usually aware of when to inhale and exhale at certain points in each posture, as breathing properly is another fundamental aspect of yoga. Breathing should be deep and through the nose. Mental concentration in each position is also very important, which improves awareness, poise and posture. During a yoga routine there is often a position in which to perform meditation, if deep relaxation is one of the goals of the sequence.

Yoga routines can take anywhere from 20 minutes to two or more hours, with one hour being a good time investment to perform a sequence of postures and a meditation. Some yoga routines, depending on the teacher and school, can be as strenuous as the most difficult workout, and some routines merely stretch and align the body while the breath and heart rate are kept slow and steady. Yoga achieves its best results when it is practiced as a daily discipline, and yoga can be a life-long exercise routine, offering deeper and more challenging positions as a practitioner becomes more adept. The basic positions can increase a person's strength, flexibility, and sense of well-being almost immediately, but it can take years to perfect and deepen them, which is an appealing and stimulating aspect of yoga for many.

Yoga is usually best learned from a yoga teacher or physical therapist, but yoga is simple enough that one can learn the basics from good books on the subject,

which are plentiful. Yoga classes are generally inexpensive, averaging around 10 dollars per class, and students can learn basic postures in just a few classes. Many YMCAs, colleges, and community health organizations offer beginning yoga classes as well, often for nominal fees. If yoga is part of a physical therapy program, its cost can be reimbursed by insurance.

Preparations

Yoga can be performed by those of any age and condition, although not all poses should be attempted by everyone. Yoga is also a very accessible form of exercise; all that is needed is a flat floor surface large enough to stretch out on, a mat or towel, and enough overhead space to fully raise the arms. It is a good activity for those who can't go to gyms, who don't like other forms of exercise, or have very busy schedules. Yoga should be done on an empty stomach, and teachers recommend waiting three or more hours after meals. Loose and comfortable clothing should be worn.

Precautions

People with injuries, medical conditions, or spinal problems should consult a doctor before beginning yoga. Those with medical conditions should find a yoga teacher who is familiar with their type of problem and who is willing to give them individual attention. Pregnant women can benefit from yoga, but should always be guided by an experienced teacher. Certain yoga positions should not be performed with a **fever** or during menstruation.

Beginners should exercise care and concentration when performing yoga postures and not try to stretch too much too quickly as injury could result. Some advanced yoga postures, like the headstand and full lotus position, can be difficult and require strength, flexibility, and gradual preparation, so beginners should get the help of a teacher before attempting them.

Yoga is not a competive sport; it does not matter how a person does in comparison with others, but how aware and disciplined one becomes with one's own body and limitations. Proper form and alignment should always be maintained during a stretch or posture, and the stretch or posture should be stopped when there is **pain**, **dizziness**, or **fatigue**. The mental component of yoga is just as important as the physical postures. Concentration and awareness of breath should not be neglected. Yoga should be done with an open, gentle, and non-critical mind; when one stretches into a yoga position, it can be thought of accepting and working on one's limits. Impatience, self-criticism, and comparing oneself to others will not help in this process of self-knowledge. While performing the yoga of breathing (pranayama) and meditation (dyana), it is best to have an experienced teacher, as these powerful techniques can cause dizziness and discomfort when done improperly.

KEY TERMS

Asana—A position or stance in yoga.

Dyana—The yoga term for meditation.

Hatha yoga—Form of yoga using postures, breathing methods and meditation.

Meditation—Technique of concentration for relaxing the mind and body.

Pranayama—Yoga breathing techniques.

Yogi (female, yogini)—A trained practitioner of yoga.

Side effects

Some people have reported injuries by performing yoga postures without proper form or concentration, or by attempting difficult positions without working up to them gradually or having appropriate supervision. Beginners sometimes report muscle soreness and fatigue after performing yoga, but these side effects diminish with practice.

Research and general acceptance

Although yoga originated in a culture very different from that of the modern United States, it has been accepted and its practice has spread relatively quickly. Many yogis are amazed at how rapidly yoga's popularity has spread in the United States and Canada, considering the legend that it was passed down secretly by handfuls of adherents for many centuries.

There can still be found some resistance to yoga, for active and busy Americans sometimes find it hard to believe that an exercise program that requires them to slow down, concentrate, and breathe deeply can be more effective than lifting weights or running. However, ongoing research in top medical schools is showing yoga's effectiveness for overall health and for specific problems, making it an increasingly acceptable health practice.

The growing acceptability of yoga as an alternative therapy for certain disorders or conditions is reflected in the fact that the National Center for Complementary and Alternative Medicine (NCCAM) is

WWW.BOOKBAZ.IR

conducting a series of clinical trials of yoga. As of December 2014, there are 281 active clinical trials in progress, evaluating yoga as a treatment for **menopause**, **post-traumatic stress disorder**, pain, arthritis etc.

Z

Zellweger syndrome

Definition

Zellweger syndrome (ZS) is the most severe of three very rare, inherited, related metabolic disorders known collectively as the Zellweger spectrum. ZS affects all of the major organs of the body, especially the brain, liver, and kidneys. It is almost always fatal within the first year of life.

Demographics

The worldwide incidence of Zellweger syndrome is estimated to be about one in 100,000 births. The incidence of Zellweger spectrum is estimated at about one in 50,000.

Description

Zellweger syndrome and the other two disorders that constitute Zellweger spectrum—neonatal **adrenoleukodystrophy** (NALD) and infantile Refsum disease (IRD)—are peroxisome biogenesis disorders (PBDs). PBDs are inherited defects or mutations in genes that are involved in the formation of peroxisomes. Peroxisomes are small sac-like compartments or organelles in all human cells. Peroxisomes are surrounded by a membrane and contain enzymes that break down or oxidize many different substances, especially fatty acids and certain toxins. For example, when large amounts of alcohol are consumed, 5 to 25 percent of the ethanol is oxidized and detoxified in peroxisomes. Peroxisomes also are important for the synthesis of some key compounds in the body, including hormones and fats (lipids) that are required by the nervous system and for digestion. Peroxisomes are especially important in the brain, liver, and kidneys. In peroxisome biogenesis disorders, defective genes prevent peroxisomes from forming correctly, resulting in an absence of peroxisomes or malformed peroxisomes that cannot perform their functions adequately.

Peroxisomes are essential for the formation and maintenance of myelin. Myelin is the substance that covers and protects nerves and promotes the efficient transmission of nerve impulses. The parts of the brain and spinal cord that contain myelin are called the white matter and include the cerebral cortex of the brain. Therefore peroxisome biogenesis disorders interfere with brain development. The destruction of the myelin (demyelination) causes the loss of white matter or leukodystrophy. Therefore, PBDs are members of a larger group of inherited disorders known as leukodystrophies. Leukodystrophies also affect the metabolism of some substances.

The brain abnormalities of Zellweger syndrome are caused by disruption of neuroblast migration in the fetus during about the third month of gestation. Neuroblasts are cells that develop into nerve cells, called neurons. This defect leads to small thick convolutions in the cerebral tissue of the brain and distinguishes Zellweger syndrome from other brain abnormalities.

After birth, defects in these same genes that cause the brain abnormalities of Zellweger syndrome also cause the reduction in or elimination of peroxisomes. The absence of peroxisomes in the liver and kidney cells of babies with Zellweger syndrome was first demonstrated in 1985 by the American pathologist S. L. Goldfischer. This absence of peroxisomes is now considered to be the hallmark of Zellweger syndrome. Babies with Zellweger syndrome also have far fewer peroxisomes in their brain cells. The fibroblasts of the skin appear to have ghost-like peroxisomes because the organelles lack certain proteins. Development of the heart, cartilage, and muscle also are affected in Zellwinger syndrome.

Risk factors

Newborns are at risk for Zellweger syndrome if each parent carries an abnormal copy of a gene responsible for the disorder. Zellweger syndrome is

WWW.BOOKBAZ.IR

inherited as an autosomal recessive trait. "Autosomal" means that the genes that are responsible for ZS are not located on the X or Y sex chromosomes and therefore affect males and females with equal frequency. "Recessive" means that Zellweger syndrome only occurs in individuals with two defective gene copies, one inherited from each parent. Although the parents each carry one copy of the mutated gene, they typically have no signs and symptoms of the condition. However each of their offspring has a 25% chance of having Zellwinger syndrome and a 50% chance of inheriting one abnormal gene, thereby becoming a ZS carrier.

Causes and symptoms

Zellweger syndrome is caused by mutations or defects in any one of several genes that encode proteins called peroxins that are essential for the formation (biogenesis) and normal functioning of peroxisomes. Peroxins produce the peroxisome membrane and import enzymes into the organelle. Mutations in at least 12 different genes can result in Zellweger spectrum. These genes are located on different chromosomes and encode distinct peroxin proteins. Defects in the peroxin–1 protein encoded by the PEX1 gene account for about 70% of Zellweger spectrum disorders. Zellweger syndrome is caused by severe defects in PEX1 or other PEX genes that result in peroxisomes that are essentially nonfunctional.

The symptoms of Zellweger syndrome are apparent at birth. They include distinct facial, developmental, and ocular (eye) features, some of which are due to high levels of iron and copper in the blood and tissues. These signs and symptoms include:

- a flattened face
- high forehead
- broad nasal bridge
- up-slanted eyes
- skin folds—called epicanthal folds—between the upper and lower eyelids along the nasal border
- underdeveloped eyebrow ridges
- deformed ear lobes
- neurological abnormalities, such as intellectual disabilities (ID) and seizures
- an enlarged liver
- severe weakness and lack of muscle tone—sometimes to the degree that the infant is unable to move, suck, or swallow
- ocular abnormalities that can affect vision, including glaucoma and retinal degeneration
- hearing impairment
- cysts on the kidneys
- sometimes jaundice or gastrointestinal bleeding

Diagnosis

Examination

Although the distinctive shape of the head and facial features are diagnostic for Zellweger spectrum, in some cases it can be difficult to distinguish between Zellweger syndrome and the other related conditions of the spectrum.

Tests

Zellweger syndrome is usually diagnosed through biochemical tests of the blood, urine, and fibroblasts. The most commonly used test is a measurement of very-long-chain fatty acids (VLCFA), which accumulate to high levels in the blood plasma with ZS. Blood levels of other fatty acids, pipecolic acid, and bile acid intermediates are also typically elevated. Plasmalogen levels are diminished.

A medical geneticist may confirm the diagnosis through detection of DNA mutations in one of the 12 different PEX genes located on chromosomes 1, 2, 6, 7, 8, 11, 12, 17, and 22. A PEX1 gene mutation is the most common cause of Zellweger syndrome. Genetic studies are accomplished with a small blood sample.

Procedures

Fatty acid levels and plasmalogen synthesis can be detected before birth using amniocentesis—the withdrawal through the mother's abdomen of fetal cells in the amniotic fluid.

Various procedures may be used to detect life-threatening problems in other organs and tissues, including the liver, heart, and kidneys. X rays can detect skeletal abnormalities, including a large space between the bones of the skull and characteristic bone spots called chondrodysplasia punctata.

Treatment

There is neither a cure for Zellweger syndrome nor a standard course of treatment. Since most of the neurological and metabolic abnormalities are caused during fetal development, treatments after birth are severely limited. The goal is to lessen symptoms and support the involved organs. In addition to physicians and nurses, physical, occupational, respiratory, and speech therapists provide supportive strategies and devices to maintain posture, independent breathing,

KEY TERMS

Amniocentesis—The insertion of a needle through the mother's abdomen into the uterus at 16–18 weeks of gestation to withdraw a small sample of the amniotic fluid surrounding the fetus to test for genetic disorders and other medical conditions.

Autosomal—Located on a chromosome other than the X or Y sex chromosomes.

Fibroblast—A connective-tissue cell.

Leukodystrophy—Any of several inherited diseases characterized by the degeneration of myelin in the brain, spinal cord, and peripheral nerves.

Myelin—Soft white material composed of lipids (fats) and protein that forms a thick sheath around nerve cells.

Neuroblast—An embryonic nerve cell that differentiates into a neuron.

Peroxins—Proteins that are responsible for forming the peroxisomal membrane and transporting other proteins into the peroxisome; these proteins are encoded by various PEX genes.

Peroxisome—A cellular organelle or microbody that contains various enzymes that are responsible for the production of cellular components and the breakdown of toxic waste products.

Peroxisome biogenesis disorder (PBD)—An inherited disorder, such as Zellweger syndrome and other Zellweger spectrum disorders, that disrupt the formation and functioning of peroxisomes.

Plasmalogen—Any of a group of phospholipids; plasmalogen synthesis is disrupted in ZS.

Recessive—A gene or trait whose effects are apparent only in the absence of a corresponding dominant gene or trait.

Zellweger spectrum—Three peroxisome biogenesis disorders—Zellwinger syndrome, neonatal adrenoleukodystrophy, and infantile Refsum disease—which can be caused by different mutations in the same genes and which differ only in the severity of the resulting condition.

eating, speech, and other developmentally appropriate activities for as long as is practical. It is important to protect against infection in order to delay the development of complications. Support services are available for family members.

Drugs

Infants may be treated with **vitamin K** to prevent abnormal bleeding. Some patients have improved with experimental therapies using docosahexaenoic acid (DHA), an omega-3 essential fatty acid that is deficient with Zellweger syndrome. The administration of bile acids, such as cholic acid or chenodeoxycholic acid, is being tested for improvement of liver function.

Prognosis

Most infants with Zellweger syndrome do not survive past their first six months and rarely live more than one year after diagnosis. Death is usually due to respiratory distress, liver failure, severe feeding difficulties, heart defects, and/or gastrointestinal bleeding.

Prevention

Because Zellweger syndrome is usually fatal within the first year of life, **genetic counseling** and prenatal diagnosis are usually a high priority for parents who are at risk of conceiving an afflicted child, particularly couples who have had a previous child with Zellweger syndrome. Prospective parents with family histories of Zellweger syndrome or spectrum may be able to undergo genetic screening to determine the likelihood of their conceiving an afflicted child.

Zika fever

Definition

Zika **fever** is a usually mild illness caused by the zika virus (ZIKV) that is transmitted through mosquito bites. In recent years, zika fever has spread from Africa and Asia to islands in the Pacific Ocean. Having spread beyond Africa and Asia, ZIKV is considered to be an emerging pathogen.

Demographics

ZIKV is endemic to Africa and Southeast Asia. It is widely distributed throughout western and eastern Africa, the Indian subcontinent, and Southeast Asia. Early studies on the virus found that 40% of tested Nigerians had antibodies against ZIKV, indicating that they had been infected with the virus at some point in time. Nevertheless until 2007, confirmed cases of zika fever were rare, probably because the disease is so mild. In 2007, a major epidemic of zika fever erupted on Yap Island in the Federated States of Micronesia in the southwestern Pacific. This was the first detection of ZIKV outside of Asia and Africa, and it came as a surprise to **public health** officials. In addition to an estimated 871 cases of zika fever, one study found that 73% of tested islanders had antibodies against the virus, suggesting that nearly 5,000 of the island's population had been infected.

Since then, zika fever has spread through the Pacific. As of 2014, there was an ongoing outbreak in French Polynesia, with some 30,000 cases since October of 2013. The outbreak spread to Easter Island and the Cook Islands where, as of March 23, 2014, there had been 49 laboratory-confirmed and 648 suspected cases. As of May 7, 2014, 1,262 laboratory-confirmed cases had been reported from New Caledonia. Imported zika fever had been reported in Japan, Australia, Germany, Canada, and the United States in travelers returning from Thailand, Indonesia, Senegal, and Bora Bora.

Description

ZIKV has not been well studied. It is a member of the *Flavivirus* genus in the Flaviviridae family of viruses. This genus also includes the viruses that cause dengue, West Nile fever, **yellow fever**, Japanese B encephalitis, and Saint Louis encephalitis. These are all arboviruses, which have single-stranded RNA as their genetic material and are transmitted by arthropods, usually mosquitoes. Arboviruses have complex life cycles: they multiply (replicate) in both their arthropod hosts and also in their vertebrate hosts, with or without causing illness. There are about 500 known arboviruses. ZIKV is closely related to the virus that causes dengue, and it causes an illness that is similar to both dengue and **chikungunya**. Since ZIKV is transmitted by at least some of the same mosquito species that transmit dengue, it has been suggested that some of the illnesses during dengue outbreaks may actually be zika fever.

ZIKV is named for the Zika Forest, near the East African Virus Research Institute in Entebbe, Uganda, where it was first isolated from the blood of a rhesus monkey in 1947. *Zika* means "overgrown" in the Luganda language. In 1948, the virus was isolated from *Aedes africanus* mosquitoes trapped in the Zika forest. Subsequently the virus has been isolated from other *Aedes* mosquito species, including *Ae. aegypti*, *Ae. africanus*, *Ae. apicoargenteus*, *Ae. luteocephalus*, *Ae. vitattus*, and *Ae. furcifer*. The virus was first isolated from human blood in Nigeria in 1954.

ZIKV is transmitted to humans primarily through bites of infected mosquitoes. ZIKV is believed to be maintained in nonhuman primate reservoirs. It is not known whether there are other nonprimate reservoir hosts for ZIKV or arthropod vectors other than *Aedes* mosquitoes. There is some evidence suggesting that ZIKV is occasionally transmitted between humans through sexual contact. In 2008, two scientists studying **malaria** in Senegal returned home to Colorado, where they both became ill with zika fever. Approximately four days later, the wife of one of the scientists also developed zika fever. Since there are no known mosquito vectors for the virus in Colorado, this suggests

that direct human-to-human transmission is possible, most likely through sexual activity. However, such transmission may only be of consequence during epidemics of the disease, and zika fever epidemics are rare. It is not known whether the virus can be transmitted from mother to infant during **pregnancy**, birth (perinatally), or **breastfeeding** or via blood transfusions.

Risk factors

The major risk factor for zika fever is being bitten by mosquitoes in regions where ZIKV is endemic or where outbreaks are occurring. The mosquitoes that carry ZIKV bite both day and night and both indoors and outdoors. They are common around buildings in urban areas, so human living conditions can contribute to their breeding. When the virus spreads to a new region, such as a Pacific Island where the population has had no previous exposure to it, most people will have no immunity to the virus, and there will be widespread illness. Furthermore, such populations often lack air conditioning or homes with good window and door screens and so are especially susceptible to mosquito bites. These factors contributed to the high number of infections observed in the affected Pacific islands.

Causes and symptoms

Causes

Although the exact cause of zika fever is unknown, in general, mosquito-borne flaviviruses such as ZIKV are thought to replicate in human immune system dendritic cells located near the site of the mosquito bite. From there, the virus spreads to the lymph nodes and bloodstream, initiating an immune response that causes the symptoms of zika fever.

Symptoms

The most common symptoms of zika fever are a bad **headache**, mild fever, **fatigue**, body rash, joint **pain** and swelling, and muscle pain that last from a few days to a week. Red eyes or **conjunctivitis** and back pain are also common. Other symptoms can include lack of appetite, **diarrhea**, **constipation**, abdominal pain, **vomiting**, and **dizziness**. **Sore throat** and **cough** may occur.

Diagnosis

Examination

Diagnosis of zika fever may be based on the symptoms and exposure to mosquito bites in regions where the virus is endemic. Recent travel to such an area may suggest the diagnosis. However, the symptoms of zika fever are easily mistaken for other arboviral infections, such as dengue or chikungunya, especially during outbreaks of those illnesses. It is important to distinguish between zika fever and dengue, because proper management of dengue can prevent the development of dengue hemorrhagic fever and significantly improve the prognosis.

Tests

ZIKV is detectable in the patient's blood from the first day of illness to at least 11 days after onset. Polymerase chain reaction (PCR) tests can be used to detect the viral RNA in the blood during the acute phase of the illness, up to nine days after onset. The Arboviral Diagnostic and Reference Laboratory of the Centers for Disease Control and Prevention (CDC), in Fort Collins, Colorado, has developed an enzyme-linked immunosorbent assay (ELISA) to detect immunoglobulin M (IgM) antibodies against ZIKV in blood serum as early as the third day after onset of illness; however, ZIKV antibodies cross-react with antibodies against other flaviviruses including the dengue virus. Thus, definitive diagnosis may be difficult in areas with other endemic flaviviruses. Antibodies that neutralize ZIKV develop as early as five days after the onset of illness, and assays to detect such neutralizing antibodies are generally more specific for ZIKV, although they can still cross-react with antibodies against other flaviviruses.

Treatment

There is no treatment or cure for zika fever. However, the illness is usually mild and self-limiting, seldom lasting more than a week to ten days.

Drugs

Non-steroidal anti-inflammatory drugs (NSAIDs)—such as ibuprofen, naproxen, **acetaminophen**, or paracetamol—or **aspirin** may help relieve the headache and reduce the fever.

Home remedies

Rest is very important for speeding recovery. It is also important to drink plenty of liquids to prevent **dehydration**.

Prognosis

As of 2014, virtually all cases of zika fever were mild and short-lived. However, **West Nile virus** was also considered to be a mild disease before large

WWW.BOOKBAZ.IR

KEY TERMS

***Aedes*—**A large genus of mosquitoes that can transmit viruses causing zika fever and related diseases.

Antibodies—Specific proteins produced by the immune system in response to specific foreign proteins or particles including viruses.

Arboviruses—RNA viruses that are primarily transmitted by mosquitoes and cause diseases such as zika fever, chikungunya, yellow fever, encephalitis, and dengue.

Chikungunya—An emerging viral disease similar to zika fever that is transmitted by mosquitoes and is spreading globally.

Conjunctivitis—Inflammation of the conjunctiva, the membrane covering the white part of the eye.

Dengue—A viral disease transmitted by *Aedes* mosquitoes with symptoms similar to zika fever.

Endemic—Restricted or peculiar to a specific locale or region; especially a disease that is prevalent only in a particular population.

Enzyme-linked immunosorbent assay (ELISA)—An immunological test for detecting specific substances, including viruses and antibodies.

Epidemic—Affecting many individuals in a community or population and spreading rapidly.

Flaviviruses—Viruses of the Flaviviridae family that are transmitted by arthropods, especially mosquitoes and ticks, including the virus that causes zika fever.

Immunoglobulin M (IgM)—A type of antibody that is produced early in an infection.

Outbreak—A sudden increase in the incidence of a disease.

Permethrin—A common neurotoxic insecticide and insect repellent that is used to treat clothing and equipment.

Polymerase chain reaction (PCR)—A powerful technique for detecting DNA or RNA from minute quantities of an infectious agent, such as a virus.

Reservoir—An animal species that harbors a virus that can be transmitted, either directly or via a vector, to humans.

West Nile virus—A virus related to ZIKV and causing an illness similar to zika fever, but which sometimes develops into encephalitis or meningitis.

ZIKV—The virus that causes zika fever.

outbreaks occurred in North America and Romania that included neurological complications in some patients.

Prevention

Outbreaks of zika fever in isolated island populations of the Pacific Ocean demonstrate that global travel and trade have the potential to spread ZIKV across large distances. The most important preventive measures in regions with endemic ZIKV or that are experiencing outbreaks of the disease involve avoiding mosquito bites. An appropriate, long-lasting mosquito repellent should be used and reapplied as directed. Repellent should not be sprayed on skin underneath clothing. Children's hands, eyes, and mouth must be carefully avoided when applying repellent. If using sunscreen, it should be applied before the repellent. Insect repellents should contain among their ingredients:

- DEET (N,N-diethyl-3-methylbenzamide or N,N-diethyl-m-toluamide), as in Off!, Cutter, Sawyer, or Ultrathon
- picaridin (2-[2-hydroxyethyl]-1-piperidinecarboxylic acid 1-methylpropyl ester or KBR 3023 in Bayrepel), as in Cutter Advanced, Skin So Soft Bug Guard Plus, and Autan outside of the United States
- oil of lemon eucalyptus (OLE) or the synthetic form PMD (para-menthane-3,8-diol), as in Repel and Off! Botanicals
- IR3535 (3-[N-butyl-N-acetyl]-aminopropionic acid, ethyl ester) as in Skin So Soft Bug Guard Plus Expedition and SkinSmart

Other measures for reducing exposure to mosquitoes and avoiding spreading disease by preventing additional mosquito bites include:

- covering exposed skin with long sleeves, long pants, and hats
- residing and sleeping in screened or air-conditioned rooms
- using mosquito coils or other insecticide vaporizers indoors
- using a bed net if sleeping exposed to the outdoors
- removing standing water
- reducing natural and artificial breeding habitats in affected communities

- spraying insecticides and applying insecticides to surfaces and in and around water containers during outbreaks
- treating water to kill immature larvae
- supporting local vector control

Permethrin-treated clothing and gear, including boots and tents, can be used. Instructions should be followed carefully. The product information should indicate how many washings the treatment can survive. Permethrin should not be applied to the skin.

Procedures for early detection of zika fever and other pathogen outbreaks are being developed by health ministries in Uganda and Vietnam, with support from the CDC and the U.S. Department of Defense Threat Reduction Agency.

Zoonosis

Definition

Zoonosis, also called *zoonotic disease*, refers to diseases that can be passed from animals, whether wild or domesticated, to humans.

Description

Although many diseases are species specific, meaning that they can only occur in one animal species, many other diseases can be spread between different animal species. These are infectious diseases, caused by bacteria, viruses, or other disease-causing organisms that can live as well in humans as in other animals.

There are different methods of transmission for different diseases. In some cases, zoonotic diseases are transferred by direct contact with infected animals, much as being near an infected human can cause the spread of an **infectious disease**. Other diseases are spread by drinking water that contains the eggs of parasites. The eggs enter the water supply from the feces of infected animals. Still others are spread by eating the flesh of infected animals. Tapeworms are spread this way. Other diseases are spread by insect vectors. An insect, such as a flea or tick, feeds on an infected animal, then feeds on a human. In the process, the insect transfers the infecting organism.

The Centers for Disease Control (CDC) in Atlanta have said that most **emerging diseases** around the world are zoonotic. The director of the CDC has said that 11 of the last 12 emerging infections in the world with serious health consequences have probably arisen from animal sources. Wild animal trade occurs across countries and many people take in wild animals as domestic pets. However, pet shops and food markets are not properly testing for diseases and parasites that can cause harm to humans and other animals.

Some zoonotic diseases are well known, such as rats (**plague**) and deer ticks (**Lyme disease**). Others are not as well known. For example, elephants may develop **tuberculosis** and spread it to humans.

WWW.BOOKBAZ.IR

Causes and symptoms

The following is a partial list of animals and the diseases that they may carry. Not all animal carriers are listed, nor are all the diseases that the various species may carry.

- Bats are important rabies carriers and also carry several other viral diseases that can affect humans.
- Cats may carry the causative organisms for plague, anthrax, cowpox, tapeworm, and many bacterial infections.
- Dogs may carry plague, tapeworm, rabies, Rocky Mountain Spotted Fever, and Lyme disease.
- Horses may carry anthrax, rabies, and *Salmonella* infections.
- Cattle may carry the organisms that cause anthrax, European tick-borne encephalitis, rabies, tapeworm, *Salmonella* infections, and many bacterial and viral diseases.
- Pigs are best known for carrying tapeworm but may also carry a large number of other infections including anthrax, influenza, and rabies.
- Sheep and goats may carry rabies, European tick-borne encephalitis, *Salmonella* infections, and many bacterial and viral diseases.
- Rabbits may carry plague and Q-Fever.
- Birds may carry *Campylobacteriosis*, *Chlamydia psittaci*, *Pasteurella multocida*, *Histoplasma capsulatum*, *Salmonellosis*, and others.

Zoonotic diseases may be spread in different ways. Tapeworms can often spread to humans when people eat the infected meat of cattle and swine. Other diseases are transferred by insect vectors, often blood-feeding insects that carry the cause of the disease from one animal to another.

Diagnosis

Diagnosis of the disease is made in the usual manner, by identifying the infecting organism. Each disease has established symptoms and tests. Identifying the carrier may be easy or may be more difficult when the cause is a fairly common infection. For example, tapeworms are usually species specific. Cattle, pigs, and fish all carry different species of tapeworms, although all can be transmitted to humans who eat undercooked meat containing live tapeworm eggs. Once the tapeworm has been identified, it is easy to tell which species the tapeworm came from.

Other zoonotic infections may be harder to identify. Sometimes the infection is fairly common among both humans and animals, and it is impossible to tell. Snakes may carry the bacteria *Escherichia coli* and *Proteus vulgaris*, but since these bacteria are already common among humans, it would be difficult to trace infections back to snakes.

Because of increased trade between nations and changes in animal habitats, there are often new zoonotic diseases. These may be found in animals transported from one nation to another, bringing with them new diseases. In some cases, changes in the environment lead to changes in the migratory habits of animal species, bringing new infections.

Treatment

Treatment is the established treatment for the specific infection.

Prevention

Prevention of zoonotic infections may take different forms, depending on the nature of the carrier and the infection.

Some zoonotic infections can be avoided by immunizing the animals that carry the disease. Pets and other domestic animals should have **rabies** vaccinations, and wild animals are immunized with an oral vaccine that is encased in a suitable bait. In some places, the bait is dropped by airplane over the range of the potential rabies carrier. When the animals eat the bait, they also ingest the oral vaccine, thereby protecting them from rabies and reducing the risk of spread of the disease. This method has been used to protect foxes, coyotes, and other wild animals.

Many zoonotic diseases that are passed by eating the meat of infected animals can be prevented by proper cooking of the infected meat. Tapeworm infestations can be prevented by cooking, and *Salmonella* infections from chickens and eggs can be prevented by being sure that both the meat and the eggs are fully cooked.

For other zoonotic diseases, programs are in place to eliminate the host, or the vector, that spreads the disease. Plague is prevented by elimination of the rats—a common source of the infection—and of fleas that carry the disease from rats to humans. Efforts around the world to control bovine spongiform encephalitis, better known as Mad Cow disease, have focused on the destruction of infected cattle to prevent spread of the disease. Regulations on the

KEY TERMS

Anthrax—A disease of warm blooded animals, particularly cattle and sheep, transmissible to humans. The disease causes severe skin and lung damage.

Bovine spongiform encephalopathy—Also known as Mad Cow disease, a progressive, fatal disease of the nervous system of domestic animals that is transmitted by eating infected food.

Lyme disease—An acute disease which is usually marked by skin rash, fever, fatigue, and chills. Left untreated, it may cause heart and nervous system damage.

Q-Fever—A disease that is marked by high fever, chills, and muscle pain. It is seen in North America, Europe, and parts of Africa. It may be spread by drinking raw milk or by tick bites.

Zoonotic—A disease which can be spread from animals to humans.

makeup of the cattle feed to ensure safety and prevent the disease have helped curb its spread.

Other means of prevention simply rely on care. People living in areas where Lyme disease is common are warned to take precautions against the bite of the deer tick, which transfers the disease. These precautions include not walking in tall grass, not walking bare legged, and wearing light-colored clothing so that the presence of the dark ticks can be readily seen.

CHRONOLOGY

165–180: The Antonine Plague, a suspected smallpox outbreak, kills upwards of 5,000 a day in Rome, Italy, possibly killing as many as five million in total.

541: The Plague of Justinian causes the death of one quarter of the Mediterranean population. It is most probably a bubonic plague.

910: Persian physician Rhazes is the first to identify smallpox, as distinguished from measles, and to suggest blood as the cause of infectious disease.

1250: Roger Bacon constructed the first magnifying glass. The magnifying power of chips of crystal had been known for centuries, but this was the first convex lens designed for scientific purposes. By about 1280, similar lenses would be used to correct farsightedness; now, they are crucial in surgery.

1338–58: The Black Death spreads across Europe, Asia, and Africa, ultimately killing around 100 million people. The cause of this pandemic was bubonic plague.

1492–1900: Europeans spread typhoid, smallpox, measles, and other disease, killing approximately 95% of the Native American population.

1590: Dutch lens grinder Zacharius Jannssen invents the microscope

1628: William Harvey publishes An Anatomical Study of the Motion of the Heart and of the Blood in Animals, describing how blood is pumped throughout the body by the heart, and then returns to the heart and recirculates. The book is very controversial but becomes the basis for modern research on the heart and blood vessels.

1656: Experimenting on dogs, English architect Sir Christopher Wren is the first to administer medications intravenously by means of an animal bladder attached to a sharpened quill. Wren also experiments with canine blood transfusions (although safe human blood transfusions only became feasible after Karl Landsteiner develops the ABO blood-typing system in 1900).

1670: Anton van Leeuwenhoek refines the microscope and fashions nearly 500 models. Discovers blood cells and observes animal and plant tissues and microorganisms.

1700: Bernardino Ramazzini (1633–1714) publishes first comprehensive occupational health treatise, which was the birth of occupational health.

1700–1800: In the United States, governmental agencies are created to address mounting health problems, sanitation and the protection of water supply, concerns that arose with the industrial revolution.

1747: James Lind , a Scottish naval surgeon, discovers that citrus fruits prevent scurvy. He publishes his Treatise of the Scurvy in 1754, identifying the cure for this common and dangerous disease of sailors, although it takes another 40 years before an official Admiralty order dictates the supply of lemon juice to ships.

1752: The earliest known document mentioning concave lenses being used for correcting myopia was a letter from the Duke of Milan to his ambassador in Florence ordering three dozen eyeglasses, including "a dozen that are suitable for near vision, that is for the elderly."

1752: Benjamin Franklin invented the flexible catheter, made of hinged metal segments, for his brother John, who suffered from bladder stones. Previously, catheters had

been hard tubes, jammed into the bladder through the urethra.

1763: Smallpox infected blankets were distributed to Native Americans starting an epidemic that killed thousands.

1779: The first recognized Dengue epidemics occur at about the same time in Asia, Africa, and North America in the 1780s. The disease was named dengue in 1779 with Benjamin Rush describing the first case report in 1789.

1793: Yellow Fever appears in the United States in the late seventeenth century. In 1793, Philadelphia is the scene of one of the worst outbreaks.

1796: Edward Jenner (1749–1843) publishes his first paper on the potential for inoculation, which led to the development of the small pox vaccine.

1799: The Lying-in Hospital of the City of New York is chartered, the first to provide obstetrical care for women in New York City.

1800: Sir Humphry Davy announces the anesthetic properties of nitrous oxide, although dentists do not begin using the gas as an anesthetic for almost 45 years.

1804: The first city water treatment plant is built in Scotland,initiating the idea that all people should have access to clean, safe drinking water.

1815: René Laënnec, a French physician, invented the stethoscope, a trumpet-shaped wooden tube, to examine a very fat woman whose heart he could not hear by pressing his ear to her chest.

1816: René Laënnec invents the stethoscope.

1816–26: The first of seven cholera outbreaks kills over 100,000 British soldiers in Europe and Asia and is believed to have spread in Calcutta from infected rice. The total number of victims is unknown.

1818: British obstetrician James Blundell performs the first successful transfusion of human blood.

1829–51: A second cholera pandemic in the United States, Asia, and Europe kills over 100,000.

1840: The first dental college, the Baltimore College of Dental Surgery, was established.

1846: Boston dentist Dr. William Morton demonstrates ether's anesthetic properties during a tooth extraction.

1849: Elizabeth Blackwell is the first woman to receive a medical degree (from Geneva Medical College in Geneva, New York).

1849: Swedish physician Magnus Huss (1807–1890) first coined the term alcoholism to systematically classify the damage that was attributable to the excessive consumption of alcohol.

1852–60: A third cholera epidemic strikes Russia. One million people die.

1860: Louis Pasteur develops pasteurization process to kill bacteria in liquids such as milk.

1863: New York City conducts the first sanitary survey. New York's Association for the Improvement of the Condition of the Poor (est. 1844) finds "dark, contracted, ill constructed, badly ventilated and disgustingly filthy" housing. Some 18,000 people live in cellar apartments whose floors are putrid mud.

1869: Dr. Robert Dalton creates the world's first hospital ambulance, a horse-drawn carriage serving Bellevue Hospital in New York.

1870s: Louis Pasteur and Robert Koch establish the germ theory of disease. According to germ theory, a specific disease is caused by a specific organism. Before this discovery, most doctors believe diseases are caused by spontaneous generation. In fact, doctors would perform autopsies on people who died of infectious diseases and then care for living patients without washing their hands, not realizing that they were therefore transmitting the disease.

1872: The American Public Health Association (APHA) founded by Dr. Stephen Smith, a physician, attorney and commissioner of New York City's Metropolitan Health Board, puts forth the concept of a national health service.

1873: The nation's first nursing school based on Florence Nightingale's principles opens at Bellevue in New York City. Nursing students work on the hospital wards 12 hours a day, six days a week. By 1910, there are more than 1,000 nursing schools in the country.

WWW.BOOKBAZ.IR

1874: Using a galvanometer, the British scientist Richard Caton noted electrical impulses from the brains of animals, laying down the principles that would lead to the development of the electroencephalogram, or EEG.

1879: The National Board of Health is established.

1879: First vaccine for cholera developed.

1881: The first anthrax vaccine is perfected by Louis Pasteur.

1882: First vaccine for rabies

1884: Sir Edwin Chadwick becomes the founding president of the Association of Public Sanitary Inspectors in England. The Association is now known as the Cartered Institute of Environmental Health.

1845–49: Famine in Ireland kills more than one million. One to two million Irish emigrate to escape the famine.

1880: Working at a military hospital in Constantine, Algeria, Dr. Alfonse Laveran discovers the parasite responsible for malaria.

1889–90: The Asiatic or Russian flu is first reported in Russia in May 1889. It spreads all over the world and within the course of a year kills over 250,000 in Western Europe alone.

1890: Naturopathy is recognized as a formal system of healthcare.

1890: Emil von Behring discovers antitoxins and uses them to develop tetanus and diphtheria vaccines.

1891: Bisphenol A is first synthesized by Russian chemist, Alexksandr Dianin.

1895: APHA publishes the *Standard Methods for the Examination of Water and Sewage*.

1895: German physicist Wilhelm Conrad Roentgen discovers X rays.

1896: First vaccine for typhoid fever.

1897: Ronald Ross, a British officer in the Indian Medical Service, demonstrates that malaria parasites are transmitted via mosquitoes, although French army surgeon Charles Louis Alphonse Laveran identified parasites in the blood of a malaria patient in 1880. The treatment for malaria was identified much earlier (and is still used today). The Qinghao plant (Artemisia annua) was described in a Chinese medical treatise from the 2nd century BCE; the active ingredient, known as artemisinin, was isolated by Chinese scientists in 1971 and is still used today. The more commonly known treatment, quinine, was derived from the bark of a tree called Peruvian bark or Cinchona and was introduced to the Spanish by indigenous people in South America during the 17th century.

1897: First vaccine for plague.

1899: Felix Hoffman develops aspirin (acetyl salicylic acid). The juice from willow tree bark had been used as early as 400 BC to relieve pain. 19th century scientists knew that it was the salicylic acid in the willow that made it work, but it irritated the lining of the mouth and stomach. Hoffman synthesizes acetyl salicylic acid, developing what is now the most widely used medicine in the world.

1900: Walter Reed reports at the APHA Annual Meeting that mosquitoes carry yellow fever.

1901: Austrian-American Karl Landsteiner describes blood compatibility and rejection (i.e., what happens when a person receives a blood transfusion from another human of either compatible or incompatible blood type), developing the ABO system of blood typing. This system classifies the bloods of human beings into A, B, AB, and O groups. Landsteiner receives the 1930 Nobel Prize for Physiology or Medicine for this discovery.

1903: Typhoid fever in Ithaca, New York, causes 82 deaths that include 29 Cornell University students. Contamination is traced to a dam construction site.

1903: Dr. Willem Einthoven of the Netherlands invented the first practical electrocardiogram. The original weighed 600 pounds, had a water cooling system for its gigantic electromagnets and needed five operators. In 1924 he received the Nobel Prize in Physiology or Medicine for his invention.

1905: APHA publishes the Standard Methods for the Examination of Milk.

1906: The first Federal Food and Drug Act passes; APHA publishes the American Journal of Public Hygiene.

1906: A typhoid outbreak in New York is traced to a cook named Mary Mallon. "Typhoid

Mary'' is a carrier of the disease but refuses to stop working. She is quarantined for life on North Brothers Island. Total number of typhus deaths reach 600 in 1906, with three victims being attributed to Mary Mallon.

1906: Sir Frederick Gowland Hopkins proposes the idea of vitamins and how they are essential to good health. Receives the 1929 Nobel Prize for Physiology or Medicine.

1907: First successful human blood transfusion using Landsteiner's ABO blood typing technique

1910: Dr. Hans Christian Jacobaeus, a Swedish internist, performed the first laparoscopy on a human. He punctured the abdominal walls of 17 patients, using cocaine as a local anesthetic, and removed fluid from their abdomens. After removing the fluid, he examined the cavities with a cytoscope.

1911: Raw milk causes streptococcus outbreak in Boston, Massachusetts, that kills 48, when it is delivered door-to-door.

1911: *Journal of the American Public Health Association* is established, later becoming the *American Journal of Public Health*.

1913: Dr. Paul Dudley White becomes one of America's first cardiologists, a doctor specializing in the heart and its functions, and a pioneer in use of the electrocardiograph, exploring its potential as a diagnostic tool.

1916: A polio epidemic kills 6,000 in the United States.

1918–19: Also known as the Spanish Flu, the influenza pandemic spreads from the United States to other parts of the world, most likely exacerbated by the movement of soldiers during World War I. An estimated 50 to 100 million people die within six months.

1919: Methamphetamine was first synthesized in Japan.

1919: Eglantyne Jebb establishes the Save the Children fund in England to aid children affected by World War I in Europe.

1919: An outbreak of botulism is responsible for killing 19 in the United States and is traced to canned olives from California.

1921: The Bureau of Indian Affairs Health Division was created.

1921: Edward Mellanby discovers vitamin D and shows that its absence causes rickets.

1922: Insulin is first used to treat diabetes.

1922: Door-to-door-delivered raw milk contaminated by streptococcus kills 22 in Portland, Oregon.

1923: First vaccine for diphtheria.

1924: Dr. Hans Berger of Germany recorded the first human electroencephalogram, or EEG. His assertion that the brain's electrical impulses could be recorded was generally met with derision, and five years passed before Dr. Berger published his technique for recording the electrical activity of the human brain from the surface of the head.

1924–25: More than 1,500 from New York, Chicago, and Washington, DC, become ill with typhoid fever from consuming oysters from Long Island, New York. One hundred fifty die.

1926: First vaccine for pertussis (whooping cough).

1927: First vaccine for tuberculosis.

1927: First vaccine for tetanus.

1928: Scottish physician Alexander Fleming (1881–1955) inadvertently discovered Penicillin while studying moulds.

1932: Save the Children spreads to the United States in order to aid children of the Great Depression.

1935: First vaccine for yellow fever.

1935: António Egas Moniz, a Portuguese neurologist, performed the first modern lobotomy, the severing of neural connections in the brain's frontal cortex to treat delusional or violent patients. He was not a trained surgeon. The operation was soon found useless and destructive and is no longer practiced, but in 1948 Moniz was awarded the Nobel Prize in Medicine or Physiology for his invention.

1935: Dr. John H. Gibbon, Jr. , successfully uses a heart-lung machine for extracorporeal circulation of a cat (i.e., all the heart and lung functions are handled by the machine while surgery is performed). Dr. Gibbon uses this method successfully on a human in 1953. It is now commonly used in open heart surgery.

1936: Dr. Albert S. Hyman demonstrated a heart pacemaker. The device was about 10 inches

WWW.BOOKBAZ.IR

long and weighed less than a pound; it supplied the heart with a current with adjustable voltage. The device, Dr. Hyman said, had been used in seven cases, although the results were good in only two of them.

1937: An Italian professor of neuropsychiatry, Dr. Ugo Cerletti, and his colleague Lucio Bini administered electroconvulsive therapy to a human patient for the first time. Of four physical therapies to treat mental illness developed in the 1930s, insulin coma therapy, Metrazol convulsive therapy, lobotomy and electroconvulsive therapy, only electroconvulsive therapy is still in use.

1937: First vaccine for typhus.

1937: Bernard Fantus starts the first blood bank at Cook County Hospital in Chicago, using a 2% solution of sodium citrate to preserve the blood. Refrigerated blood lasts ten days.

1938: Fair Labor Standards Act (FLSA). Passed as part of President Roosevelt's New Deal, FLSA provided regulations for employers to improve conditions of workers.

1942: The Oxford Committee for Famine Relief (Oxfam) is founded in Britain to help get food to women and children starving in enemy-occupied Greece during World War II.

1943: Microbiologist Selman A. Waksman discovers the antibiotic streptomycin, later used in the treatment of tuberculosis and other diseases.

1943: Willem J. Kolff, a Dutch physician, built the first dialysis machine, working with tin cans and parts from washing machines during the Nazi occupation of the Netherlands. Although his first few attempts were failures, Dr. Kolff did finally develop a useful machine in the 1950s while working with colleagues at the Cleveland Clinic.

1944: David S. Sheridan, a man with an eighth-grade education working in a floor refinishing business, invented the disposable catheter, a hollow plastic tube designed to be used once and discarded. He founded four successful companies, held more than 50 patents and died in 2004, at age 95.

1944: The National Health Service is founded in Great Britain.

1945: First vaccine for influenza.

1946: Centers for Disease Control and Prevention (CDC) was established in 1946 in Atlanta as the Communicable Disease Center.

1947: American cardiac surgeon Claude Schaeffer Beck (1894–1971) was the first to use a defibrillator on a human when he successfully applied it to a 14-year-old male during surgery.

1948: United Nations establishes the World Health Organization.

1949: National Institute of Mental Health is founded.

1950: Jonas Salk introduces Salk vaccine for polio.

1950: Mass TB immunization with the bacille Calmette-Guerin (BCG) vaccine is under way to protect children from tuberculosis.

1950: Dr. Harold Ridley, a British ophthalmologist, implanted the first permanently placed intraocular lens to correct cataract.

1952: The Great Smog of London kills as many as 12,000.

1952: In the United States, polio takes the lives of 3,000.

1952: Paul Zoll develops the first cardiac pacemaker to control irregular heartbeat.

1952: Henry Opitek, 41, was operated on using an artificial heart, the Dodrill GMR heart machine, manufactured by General Motors and generally considered the first mechanical heart. The surgeon, Dr. Forest Dewey Dodrill, successfully repaired the patient's mitral valve, and Mr. Opitek lived until 1981.

1952: The Nobel Prize in Physics was awarded to Felix Bloch and Edward Mills Purcell for their work in developing nuclear magnetic resonance, the principle behind M.R.I. machines.

1953: Dr. John Heysham Gibbon used his new invention, the heart-lung bypass machine, for the first time in open-heart surgery, completely supporting a patient's heart and lung functions for about half the time of the surgery. It was the culmination of his decades of work in developing the machine.

1953: Dr. André Djourno of France developed a cochlear prosthesis, a method of stimulating the cochlear nerve in deaf people. It was the beginning of the long road to the development of effective cochlear implants. In 1957, he performed the first cochlear implantation. He believed that medical devices should remain in the public domain and refused to patent his invention.

1953: James Watson and Francis Crick at Cambridge University describe the structure of the DNA molecule. Maurice Wilkins and Rosalind Franklin at King's College in London are also studying DNA. (Wilkins in fact shares Franklin's data with Watson and Crick without her knowledge.) Watson, Crick, and Wilkins share the Nobel Prize for Physiology or Medicine in 1962 (Franklin had died and the Nobel Prize only goes to living recipients).

1953–87: Camp Lejeune water supply is contaminated with harmful chemicals that sicken military personnel and their families.

1954: Dr. Joseph E. Murray performs the first kidney transplant between identical twins.

1955: The polio vaccine virtually eradicates polio from the United States.

1956: National Library of Medicine established.

1957: Dr. Willem Kolff and Dr. Tetsuzo Akutzu implant the first artificial heart in a dog. The animal survives 90 minutes.

1958: Dr. Seymour Furman, a cardiologist at Montefiore Hospital in the Bronx, succeeded in extending a patient's life by more than two months using a cardiac pacemaker, a large machine to which the patient was attached by a 50-foot extension cord. By the next year, portable versions of the machine were in use.

1958: Dr. Edward Hon of Yale reported using a Doppler monitor on a woman's abdomen to detect fetal heartbeat. Ultrasound's principles had been known for more than a century (a Swedish physicist, Christian Andreas Doppler, gave his name to the phenomenon in 1842), but this was its first use in prenatal care.

1960: G. D. Searle & Company receives FDA approval to sell Enovid as a birth control pill. The development of the first highly effective contraceptive transforms women's lives around the world and opens the door to the sexual revolution.

1961: Dr. Thomas J. Fogarty came up with the idea for the balloon embolectomy catheter for removing blood clots, and used it on a patient six weeks later. It was the first minimally invasive surgery technique.

1962: President John F. Kennedy signed into law the Migrant Health Act, which provided for the establishment of health clinics across the nation designed to deal specifically with migrant health issues.

1963: Paul Winchell, the ventriloquist and inventor, patented the first artificial heart, developed in collaboration with Dr. Henry J. Heimlich, later famous for the Heimlich maneuver.

1963: The first human liver transplant was performed by Dr. Thomas E. Starzl. The patient, a 3-year-old child, rapidly bled to death.

1964: First vaccine for measles.

1964: Surgeon General's Report on Smoking and Health published; President Johnson signs the Medicare/Medicaid Act.

1965: The Johnson Administration created Medicare and Medicaid.

1965: The first report on diabetes mellitus is issued.

1965: Walter Erich Krause of the Siemens Corporation filed a patent for the first practical commercial ultrasound machine. According to the patent, his machine could be "used for practical ultra-sonic-optical examination to achieve a lifelike reproduction of the body part under examination."

1967: First vaccine for mumps.

1967: South African heart surgeon Dr. Christiaan Barnard performs the first human heart transplant.

1968: Noroviruses are named after the original strain that caused an outbreak of gastroenteritis in a Norwalk, Ohio school.

1969: Federal Coal Mine Health and Safety Act of 1969 passes in the United States.

1970: Congress establishes the Environmental Protection Agency(EPA); the Occupational

WWW.BOOKBAZ.IR

Safety and Health Administration (OSHA); and the National Institute for Occupational Safety and Health (NIOSH).

1970: The Occupational Safety and Health Act of 1970 was passed, which requires employers to create a workplace free of known hazards.

1970: First vaccine for rubella.

1970: Amendments to the Clean Air Act greatly expand its effectiveness.

1971: The first commercial CT scanner, developed by Dr. Godfrey Hounsfield, was used on a patient in London. Dr. Hounsfield shared the 1979 Nobel Prize in Physiology or Medicine for his invention.

1972: The Clean Water Act passes.

1972: The Special Supplemental Nutrition Program for Women, Infants, and Children, commonly referred to as WIC, a federally funded nutrition-intervention program administered by the food and Nutrition Service of the U.S. Department of Agriculture, was founded.

1973: The American Psychiatric Association removed homosexuality from their list of mental disorders.

1973: An inventor and entrepreneur, Dean L. Kamen, patented the first insulin pump. He became perhaps even better known for a later invention, the Segway transporter.

1973: Roe v. Wade is decided by the U.S. Supreme Court. The court rules that laws prohibiting abortions violate a constitutional right to privacy. Texas attorney Sarah Weddington argues the case on behalf of "Jane Roe."

1974: First vaccine for chicken pox.

1975: First cases of Lyme disease discovered in Lyme, Connecticut, where the disease got its name.

1976: Two hundred twenty-one attendees of the American Legion conference in Philadelphia fall ill and 34 die. The disease is called Legionaire's disease.

1977: The U.S. Consumer Product Safety Commission announces a ban on lead paint on toys and furniture, nearly 60 years after studies show that lead is dangerous to children and decades of opposition from the lead industry.

1977: First vaccine for pneumonia.

1978: First vaccine for meningitis.

1978: First test-tube baby is born in the U.K.

1978: Dr. Raymond V. Damadian announced that he had patented a technique using nuclear magnetic resonance to distinguish between normal and cancerous tissue. In 2003, two other researchers won a Nobel Prize for further discoveries.

1979: Anthrax outbreak in the Soviet Union suspected to be caused by secret bioweapons lab.

1979: Three Mile Island nuclear power station suffers a heating of the core but not a full reactor meltdown. Thirteen million curies of radioactive gases is released. The INES rating is a 5, meaning it is an accident with wider consequences. No deaths are attributed to the accident.

1980: The World Health Organization announces the eradication of smallpox.

1980: The American Psychological Association adds Post Traumatic Stress Syndrome (PTSD) to its DSM-III (Diagnostic and Statistical Manual of Mental Disorders) classification system.

1981: AIDS epidemic; CDC begins to report cases of rare pneumonia and cancers in youn gay men. This marks the beginning of the AIDS/HIV epidemic though the virus was present previously.

1981: First vaccine for hepatitis B is introduced.

1982: Acquired Immune Deficiency Syndrome (AIDS) becomes an established term.

1982: Dr. William DeVries implants the Jarvik-7 artificial heart into patient Barney Clark. Clark lives 112 days.

1984: Salmonella used by cult to contaminate salad bars in rural Oregon caused 750 cases.

1984–85: Famine in Ethiopia gets worldwide attention that culminates in Live Aid concerts around the world.

1984: The Union Carbide plant in Bhopal, India, leaks an estimated 32 tons of toxic gases, leading to approximately 20,000 deaths.

1985: Listeria-contaminated Mexican cheese produced in Los Angeles sickens Hispanic women, many whom were pregnant. Twenty-eight die.

1985: Times Beach, Missouri, evacuates and becomes a ghosttown in the aftermath of EPA findings confirming years of DDT contamination.

1986: Chernobyl nuclear power station melts down during a safety check of the system. WHO estimates 9,000 victims of the meltdown. The International Nuclear and Radiological Event Scale (INES) ranks Chernobyl a 7, meaning it is a major long-term impact on humans and the environment.

1987: Global AIDS initiative started by the World Health Organization.

1987: The F.D.A. approves Prozac, which becomes the most prescribed antidepressant drug worldwide.

1988: Congress passed the Medical Waste Tracking Act of 1988.

1989: The Kids in the Environment project in California launches children's environmental health (CEH) initiatives in the United States.

1989: The first synthetic blood, Fluosol-DA, was approved for human use. It was withdrawn from the market in 1994. The search for a blood substitute goes on, and there is none in use in clinical practice.

1990: The Nutrition Labeling Education Act was signed into law. The act required food manufacturers to disclose the fat (saturated and unsaturated), cholesterol, sodium, sugar, fiber, protein and carbohydrate content in their products.

1991–92: Drought and civil war cause famine in Somalia. An estimated 300,000 deaths occur.

1992: Dr. Leroy E. Hood patents his invention of the automated DNA sequencing technique. The patent is owned by the California Institute of Technology.

1992: A paper in the journal Magnetic Resonance Medicine by a group of researchers at the Medical College of Wisconsin announced the first use of functional magnetic resonance imaging to detect brain blood flow in conjunction with a human mental activity.

1992: First vaccine for hepatitis A is introduced.

1994: Medicine and Public Health Initiative established by the APHA and American Medical Association.

1994: U.S. Congress passed the Violence Against Women Act, which established the Rape Prevention and Education(RPE) program at the CDC.

1995: Former President Bill Clinton proclaims the first full week of April as National Public Health Week.

1995: Religious cult release sarin gas in Tokyo subway killing 12.

1996: Dolly the sheep becomes the first mammal cloned from an adult cell (dies in 2003).

1997: Prior to her death, Diana, Princess of Wales, supports the cause to ban land mines. Her support brings public awareness to the health and safety problems caused by land mines left in conflict areas.

1998: Twenty-one people die from listeria-contaminated Ball Park brand hot dogs and Sara Lee deli meats processed at a Michigan plant.

1998: First vaccine for lyme disease.

2000: First draft of human genome is announced; the finalized version is released three years later.

2001: September 11th terrorist attacks result in almost 3,000 deaths. Subsequent illness and deaths associated with exposure during the attacks will continue to be assessed.

2001: Anthrax letters sent to 5 media outlets and 2 senators offices sickened 22 people and killed 5.

2002: Listeria-contaminated Pilgrim's Pride brand turkey meats sicken people in multiple states and cause eight deaths.

2002: The Public Health Security and Bioterrorism Preparedness and Response Act of 2002 provided grants to improve hospitals' preparedness to respond to bioterrorism and other public health emergencies.

2003: Severe acute respiratory syndrome, or SARS, is a contagious and potentially fatal disease that first appeared in the form of a multi-country outbreak in early February 2003.

2004: Earthquake with 9.1 magnitude hits off the coast of Sumatra, causing catastrophic

WWW.BOOKBAZ.IR

tsunami that hits 14 countries. Over 225,000 people die and 1.7 million are displaced.

2004: Fourth death is attributed to avian flu in Vietnam.

2004: The Rheo knee, a plastic prosthetic joint that adapts to a user's walking style and changes in terrain, is produced by the Ossur Corporation.

2005: Hurricane Katrina hits New Orleans, causing levees to break and widespread devastation creates an environmental health crisis. Approximately 2,000 people die.

2005: The continued spread of a highly pathogenic avian influenza virus across eastern Asia and other countries raised concerns about a potential human pandemic.

2005: The first partial face transplant is conducted in France.

2006: APHA launches Get Ready campaign, an all hazards preparedness initiative.

2006: Former Soviet KGB agent tests positive for polonium and dies in London.

2006: E. coli O157:H7 outbreak involving bagged spinach grown at Paicines Ranch in San Benito County, California. There were five fatalities in that outbreak, in which about 200 people became ill after eating bagged spinach.

2006: Two vaccines are introduced to protect against human papilloma viruses that can cause cervical cancer and genital warts. HPV is the most common sexually transmitted virus in the United States.

2006: A "mini-liver"—the size of a small coin—is generated from human cord blood stem cells by Dr. Colin McGucklin and Dr. Nico Forraz at Newcastle University, U.K.

2007: Scientists discover how to use human skin cells to create embryonic stem cells.

2008: Babies in China are poisoned by melamine in Chinese-produced infant formula. At least three babies die. Melamine is the same chemical found to sicken and kill pets in 2007 Chinese-produced pet food.

2008: Cyclone kills 22,000 in Myanmar.

2008: An earthquake in Sichuan Province in China kills 50,000.

2008–09: Cholera outbreak in Zimbabwe takes over 4,000 lives.

2008–09: Contamination of peanut butter with salmonella typhimurium causes 714 to become ill across 46 states. Nine die.

2009: Over 15,000 die worldwide from influenza.

2009: Swine flu victims reach 60 in Mexico as the world faces a possible pandemic with the H1N1 virus.

2009: Australian bush fires claim 181 lives.

2010: Earthquake with a 7.0 magnitude strikes Haiti, killing over 300,000, injuring over 300,000, and displacing over 1 million people. An outbreak of cholera rises.

2010: Deepwater Horizon oil spill leaks an estimated 155 million gallons of oil into the Gulf of Mexico. The initial explosion kills 11 people. Long-term health effects is unknown.

2010: An industrial accident releases 35 million cubic feet (1 million cubic meters) of liquid alumina sludge in western Hungary. Approximately nine people die and 122 are injured.

2010: First full face transplant is carried out in Spain.

2010: More than 1,100 die in Pakistan floods.

2009: President Barack Obama signs the Family Smoking Prevention and Tobacco Control Act, which gives the F.D.A. the power to regulate nicotine and ban tobacco advertising aimed at children.

2010: President Barack Obama signs the Affordable Health Care for America Act, with the intent of enabling millions of Americans to obtain health insurance.

2011: Cantaloupes from Colorado spread listeria across 28 states, sickening 146 and killing 36.

2011: The Joplin, Missouri, tornado kills 117 and is one of the deadliest in U.S. history.

2011–12: Haiti fights cholera outbreaks since the 2010 earthquake. Over 6,500 people die.

2011–12: East Africa drought causes famine in Somalia.

2011: A bionic eye becomes available in Europe. It is approved by the FDA for use in the United States in 2014.

2011: Fukushima Daiichi nuclear power station meltdown rates an INES 7 as one of the

worst nuclear disasters. The nuclear meltdown occurrs following an earthquake and devastating tsunami hits the Japanese coast.

2012: The United States experiences an outbreak of fungal meningitis that kills 15 and a rash of necrotizing fasciitis cases during the summer. Hantavirus causes deaths of campers at Yellowstone National Park.

2012: Eleven people die in Cuba from Hurricane Sandy. The United States sustains catastrophic flooding in the most populated areas of New York City and the East Coast. Forty people die as a result of the super storm.

2013: A Carnival cruise ship takes five days after a fire cuts power onboard to reach port. Passengers face questionable sanitary conditions and cruise ship health is brought to the attention of the public.

2013: A meteor injures at least 950 when it crashes in the Ural mountains near Chelyabinsk, Russia.

2013: A new device to combat intractable epilepsy suffered by approximately 30% of epileptics gains backing from the FDA. Implanted under the skull, the device detects activity leading up to a seizure, sends out electrical pulses, and stops the seizure from occurring.

2014: The Ebola Outbreak in West Africa is the largest in history, affecting the entire countries of Liberia, Sierra Leone, and Guinea. It spreads to Nigeria, Senegal, and Mali. Cases are reported in Spain, the United States, Scotland, and England. Total cases top 24,000 with close to 10,000 deaths.

2014: The FDA approves the first human clinical trials in the United States for a wearable artificial kidney designed by Blood Purification Technologies Inc. out of Beverly Hills, California.

2014–2015: The United States experiences the most measles cases since the eradication of the disease in the United States in 2000. In early 2015, a multi-state outbreak is linked to a California amusement park. A sharp increase in cases worldwide also sparks the World Health Organization to demand countries control outbreaks.

ORGANIZATIONS

The following is an alphabetical compilation of relevant organizations listed in the *Resources* sections of the main body entries. Although the list is comprehensive, it is by no means exhaustive. It is a starting point for gathering further information. Many of the organizations listed provide information for multiple disorders and have links to additional related websites. E-mail addresses and web addresses listed were provided by the associations; Gale, Cengage Learning is not responsible for the accuracy of the addresses or the contents of the websites.

5p-Society
7108 Katella Ave. no. 502
Stanton, CA 96080
Phone: (562) 804-4506
Fax: (562) 920-5240
Toll free: (888) 970-0777
E-mail: director@fivepminus.org

GLOSSARY

The glossary is an alphabetical compilation of terms and definitions listed in the *Key Terms* sections of the main body entries. Although the list is comprehensive, it is by no means exhaustive.

A

AADC INHIBITORS. Drugs that block the amino acid decarboxylase; one type of enzyme that breaks down dopamine. Also called DC inhibitors, they include carbidopa and benserazide.

ABDOMINAL ANEURYSM. Aneurysm that involves the descending aorta from the diaphragm to the point at which it separates into two iliac arteries.

ABDOMINAL AORTIC ANEURYSM. Occurs when an area in the aorta (the main artery of the heart) is weakened and bulges like a balloon. The abdominal section of the aorta supplies blood to the lower body.

ABDOMINAL DISTENSION. Swelling of the abdominal cavity, which creates painful pressure on the internal organs.

ABDOMINAL MIGRAINE. A variant form of a migraine headache; moderate to severe midline abdominal pain, usually occurring in children with a family history of migraine. Sometimes referred to as chronic vomiting syndrome (CVS).

ABLATION. The removal of abnormal tissue growths by surgery.

ABLATION THERAPY. A procedure used to treat arrhythmias, especially atrial fibrillation. During the procedure, a catheter (small flexible tube) is inserted into a vein and threaded to the heart. High-frequency electrical energy is delivered through the catheter to disconnect the pathway causing the abnormal heart rhythm in the heart.

ABLATIVE. Used to describe a procedure involving removal of a tissue or body part, or destruction of its function.

ABO ANTIGEN. Protein molecules located on the surfaces of red blood cells that determine a person's blood type: A, B, or O.

ABO BLOOD GROUPS. A system in which human blood is classified according to the A and B antigens found in red blood cells. Type A blood has the A antigen, type B has the B antigen, AB has both, and O has neither.

ABO BLOOD TYPE. Blood type based on the presence or absence of the A and B antigens on the red blood cells.

ABORTIVE. Referring to treatment that relieves symptoms of a disorder.

ABRASION. Also called a scrape. The rubbing away of the skin surface by friction against another rough surface.

ABROVIRUS VIRUSES. Also known as arthropod-borne viruses, these viruses are maintained in nature through biological transmission between vertebrate hosts and blood-feeding arthropods. Infection occurs when an infected arthropod, such as a mosquito, feeds off a vertebrate, such as a human.

ABSCESS. A cavity containing pus surrounded by inflamed tissue.

ABSORPTION. The transfer of a vitamin from the digestive tract to the bloodstream.

ABSORPTION SPECTROMETRY. A scientific procedure to determine chemical makeup of samples.

ABSTINENCE. Refraining from the use or indulgence of something, commonly alcoholic beverages or sexual activity.

ABUTMENT TOOTH. A crowned tooth that stabilizes a bridge or partial denture.

ACALCULOUS CHOLECYSTITIS. Inflammation of the gallbladder that occurs without the presence of gallstones.

ACAMPROSATE. An anti-craving medication used in Europe to reduce the craving for alcohol. It is presently undergoing tests for approval in the United States.

ACANTHOSIS NIGRICANS. A dark brownish or blackish discoloration of the skin related to overweight and high levels of insulin in the blood. Acanthosis nigricans is most likely to develop in the groin or armpits, or around the back of the neck.

ACCESS SITE. The vein tapped for vascular access in hemodialysis treatments. For patients with temporary treatment needs, access to the bloodstream is gained by inserting a catheter into the subclavian vein near the patient's collarbone. Patients in long-term dialysis require stronger, more durable access sites, called fistulas or grafts, that are surgically created.

ACCESSORY ORGAN. A lump of tissue adjacent to an organ that is similar to it, but which serves no important purpose, if functional at all. While not necessarily harmful, such organs can cause problems if they grow too large or become cancerous. In any case, their presence points to an underlying abnormality in the parent organ.

ACCOMMODATION. The ability of the eye to change its focus from distant to near objects. It is achieved through the action of the ciliary muscles that change the shape of the lens.

ACETABULUM. The large cup-shaped cavity at the junction of pelvis and femur or thigh bone.

ACETAMINOPHEN. A drug for relieving pain and fever. Tylenol is the most common example.

ACETIC ACID. Vinegar; very dilute washes of the treated areas with a vinegar solution are suggested by some surgeons after laser skin resurfacing.

ACETYLCHOLINE. A chemical called a neurotransmitter that functions to excite nerve cells.

ACETYLCHOLINESTERASE. An enzyme that breaks down acetylcholine.

ACHALASIA. Failure of the lower end of the esophagus (or another tubular valve) to open, resulting in obstruction, either partial or complete.

ACHLORHYDRIA. An abnormal condition in which hydrochloric acid is absent from the secretions of the gastric glands in the stomach.

ACHROMATOPSIA. The inability to distinguish any colors.

ACID. Common street name for LSD.

ACID-BASE BALANCE. A balance of acidity and alkalinity of fluids in the body that keeps the pH level of blood around 7.35–7.45.

ACID-FAST STAIN. A special stain done to microscopically identify the bacteria that cause tuberculosis.

ACID INDIGESTION. Stomach discomfort that results from too much acid in the stomach.

ACIDOPHILUS. The bacteria *Lactobacillus acidophilus*, usually found in yogurt and used to combat yeast infections.

ACIDOSIS. A medical condition caused by an increase in the concentration of hydrogen ions in the blood. The result of this increase is a lowered (acidic) blood pH level.

ACINAR CELL CARCINOMA. A malignant tumor arising from the acinar cells of the pancreas.

ACNE. A chronic inflammation of the sebaceous glands that manifests as blackheads, whiteheads, and/or pustules on the face or trunk.

ACOUSTIC NEUROMA. A benign tumor that grows on the nerve leading from the inner ear to the brain. As the tumor grows, it exerts pressure on the inner ear and causes severe vertigo.

ACOUSTIC WINDOW. Area through which ultrasound waves move freely.

ACQUIRED IMMUNE DEFICIENCY SYNDROME (AIDS). A group of diseases resulting from infection with the human immunodeficiency virus (HIV). A person infected with HIV gradually loses immune function, becoming less able to resist aliments and cancers, resulting in eventual death.

ACROCYANOSIS. A slight cyanosis, or blueness of the hands and feet of the neonate is considered normal. This impaired ability to fully oxygenate the extremities is due to an immature circulatory system which is still in flux.

ACROMEGALY. A rare disease resulting from excessive growth hormone caused by a benign tumor. If such a tumor develops within the first 10 years of life, the result is gigantism (in which growth is accelerated) and not acromegaly. Symptoms include coarsening of the facial features, enlargement of the hands, feet, ears, and nose, jutting of the jaw, and a long face.

ACTINIC KERATOSIS. A precancerous skin condition in which skin exposed to the sun forms thick, scaly, or crusty patches. Untreated actinic keratosis has a 20% chance of progressing to skin cancer.

ACTIVATED PARTIAL THROMBOPLASTIN TIME. Partial thromboplastin time test that uses activators to shorten the clotting time, making it more useful for heparin monitoring.

WWW.BOOKBAZ.IR

ACTIVE IMMUNIZATION. Treatment that provides immunity by challenging an individual's own immune system to produce antibody against a particular organism, in this case the rabies virus.

ACTIVE TREATMENT STAGE. The period during which orthodontic appliances or braces are used.

ACTIVITIES OF DAILY LIVING (ADLS). A general term for routine activities of self-care (e.g., brushing teeth, dressing oneself, bathing) and functioning independently (e.g., managing money, preparing meals, cleaning house).

ACUPOINT. A pressure point stimulated in acupressure.

ACUPRESSURE. Often described as acupuncture without needles, acupressure is a traditional Chinese medical technique based on the theory of *qi* (life energy) flowing in energy meridians or channels in the body. Applying pressure with the thumb and fingers to acupressure points is thought to relieve specific conditions and promote overall balance and health.

ACUPUNCTURE. Acupuncture is a traditional Chinese medical technique based on the theory of *qi* (life energy) flowing in energy meridians or channels in the body. The placement of thin needles to acupressure points is thought to relieve specific conditions and promote overall balance and health.

ACUTE. Disease or condition characterized by the rapid onset of severe symptoms.

ACUTE KIDNEY INJURY (AKI). Damage to the kidney from toxic substances, as can occur with rhabdomyolysis.

ACUTE LYMPHOBLASTIC LEUKEMIA (ALL). A type of leukemia, also called acute lymphocytic leukemia, primarily in children, affecting lymphocytes.

ACUTE OTITIS MEDIA. Inflammation of the middle ear with signs of infection lasting less than three months.

ACUTE PAIN. Pain in response to injury or another stimulus that resolves when the injury heals or the stimulus is removed.

ACUTE PHASE REACTANT. A substance in the blood that increases as a response to an acute conditions such as infection, injury, tissue destruction, some cancers, burns, surgery, or trauma.

ACUTE PRESCRIBING. Homeopathic treatment for self-limiting illnesses with abrupt onset.

ACUTE RENAL FAILURE (ARF). The sudden loss of the kidneys' ability to filter waste products from the blood.

ACUTE RESPIRATORY DISTRESS SYNDROME. A serious reaction to various forms of injuries to the lung, which is characterized by inflammation of the lung, leading to impaired gas exchange and release of inflammatory mediators causing inflammation and low blood oxygen and frequently resulting in multiple organ failure. This condition is life threatening and often lethal, usually requiring mechanical ventilation and admission to an intensive care unit.

ACUTE RETROVIRAL SYNDROME (ARS). Nausea, vomiting, fever, headache, general fatigue, and muscle cramps that develop in about 30% of patients within a few weeks of HIV infection.

ACYCLOVIR. An antiviral drug that is available in oral, intravenous, and topical forms and that blocks replication of the varicella zoster virus.

ADAPTIVE FUNCTIONING. A term used to describe a person's having the intellectual, social, and practical skills needed to live independently.

ADAPTIVE IMMUNE SYSTEM. The part of the immune system that develops responses to specific antigens and maintains immunological memory. It is also known as the acquired immune system.

ADDED SUGAR. Sugar that is added to foods during processing, preparation, or eating.

ADDICTION. The state of being both physically and psychologically dependent on a substance.

ADDICTIVE PERSONALITY. The concept that addiction is the result of pre-existing character defects.

ADDISON'S DISEASE. A disease characterized by a deficiency in adrenocortical hormones due to destruction of the adrenal gland.

ADENOCARCINOMA. A malignant tumor that arises within the tissues of a gland and retains its glandular structure.

ADENOIDS. Lymph glands just above the tonsils and the palate.

ADENOMA. A type of noncancerous (benign) tumor that often involves the overgrowth of certain cells of the type normally found within glands.

ADENOMYOSIS. Uterine thickening caused when endometrial tissue, which normally lines the uterus, extends outward into the fibrous and muscular tissue of the uterus.

ADENOSINE. A nucleoside that plays multiple physiological roles in energy transfer and molecular signaling, as a component of RNA, and as an inhibitory neurotransmitter that promotes sleep.

ADENOSINE DEAMINASE (ADA). An enzyme that is lacking in a specific type of SCID. Children with an ADA deficiency have low levels of both B and T cells.

ADENOVIRUS. A virus that affects the upper respiratory tract.

ADEQUATE INTAKE (AI). The daily average intake level of a nutrient that is likely to be adequate for a healthy, moderately active individual, as determined by the U.S. Institute of Medicine.

ADHESION. Web-like scar tissue that may develop as a result of surgery or a disease such as endometriosis and bind organs to one another.

ADIPOSE TISSUE. Fat tissue.

ADJUNCTIVE. Refers to a form of treatment that is not strictly necessary to a therapy regimen but is helpful. Music therapy is an example of an adjunctive form of treatment.

ADJUSTMENT. A specific type of manipulation of the spine designed to return it to proper structural and functional form.

ADJUSTMENT DISORDER. A disorder defined by the development of significant emotional or behavioral symptoms in response to a stressful event or series of events within the normal range of human experience.

ADJUVANT. A substance added to a vaccine to increase the immune system's response to the vaccine contents.

ADJUVANT CHEMOTHERAPY. Treatment of the tumor with drugs after surgery to kill as many of the remaining cancer cells as possible.

ADJUVANT THERAPY. Treatment involving radiation, chemotherapy (drug treatment), hormone therapy, biotherapeutics, or a combination of any of these given after the primary treatment in order to rid the body of residual microscopic cancer.

ADRENAL CORTEX. The outer tissue of the adrenal gland. It produces a group of chemically related hormones called corticosteroids that control mineral and water balance in the body and include aldosterone and cortisol.

ADRENAL GLAND. An endocrine gland located above each kidney. The inner part of each gland secretes epinephrine (adrenaline) and the outer part secretes steroid hormones.

ADRENAL MEDULLA. The inner tissue of the adrenal gland. It produces the hormones adrenaline and noradrenaline.

ADRENERGIC. Refers to neurons (nerve cells) that use catecholamines as neurotransmitters at a synapse.

ADRENERGIC RECEPTOR. There are three families of adrenergic receptors, alpha$_1$, alpha$_2$ and beta, and each family contains three distinct subtypes. Each of the nine subtypes are coded by separate genes, and display specific drug specificities and regulatory properties.

ADRENOCORTICOTROPIC HORMONE (ACTH). A pituitary hormone that stimulates the cortex of the adrenal glands to produce adrenal cortical hormones.

ADRENOCORTICOTROPIN (CORTICOTROPHIN). A hormone that acts on cells of the adrenal cortex, causing them to produce male sex hormones and hormones that control water and mineral balance in the body.

ADSORPTION. The binding of a chemical (e.g., drug or poison) to a solid material such as activated charcoal or clay.

ADVANCE DIRECTIVE. A general term for two types of documents, living wills and medical powers of attorney, that allow people to give instructions about health care in the event that they cannot speak for themselves.

ADVANCED BREAST BIOPSY INSTRUMENT (ABBI). Uses a rotating circular knife and thin heated electrical wire to remove a large cylinder of abnormal breast tissue.

ADVANCED MEDICAL DIRECTIVE. A legal document drafted by a patient, in advance, ordering specific medical procedures to be offered or withheld if they are incapacitated.

AEDES. A large genus of mosquitoes, such as *Ae. aegypti* and *Ae. aldopictus*, that can transmit chikungunya and related viruses.

AEROBE. Bacteria that require oxygen to live.

AEROBIC. Organism that grows and thrives only in environments containing oxygen.

AEROBIC BACTERIA. Bacteria that require oxygen in order to grow and survive.

AEROBIC EXERCISE. Any exercise that increases the body's oxygen consumption and improves the functioning of the cardiovascular and respiratory systems.

WWW.BOOKBAZ.IR

AEROSOLS. Sprays that contain propellants and solvents, including many household products.

AFFECT. An observed emotional expression or response.

AFFECTIVE DISORDER. An emotional disorder involving abnormal highs and/or lows in mood.

AFFECTIVE FLATTENING. A loss or lack of emotional expressiveness. It is sometimes called blunted or restricted affect.

AFFERENT. Refers to peripheral nerves that transmit signals to the spinal cord and the brain. These nerves carry out sensory function.

AFFERENT NERVE FIBER. A nerve fiber in a receptor or a sense organ that carries nerve impulses toward the central nervous system.

AFLATOXIN. A substance produced by molds that grow on rice and peanuts. Exposure to aflatoxin is thought to explain the high rates of primary liver cancer in Africa and parts of Asia.

AFLATOXINS. A group of naturally occurring toxins produced by fungi of the genus *Aspergillus*.

AFRICAN ENDEMIC KAPOSI'S SARCOMA. A form of KS that affects men and boys and that can appear like classic KS or in a more lethal form.

AGAMMAGLOBULINEMIA. The lack of gamma globulins in the blood. Antibodies are the main gamma globulins of interest, so this term means a lack of antibodies.

AGAR. A gel made from red algae that is used to culture certain disease agents in the laboratory.

AGAVE NECTAR. A sweetener produced commercially in Mexico from the leaves of agave, a succulent plant with thick fleshy leaves.

AGE-RELATED MACULAR DEGENERATION (ARMD). Degeneration of the macula (the central part of the retina where the rods and cones are most dense) that leads to loss of central vision in people over 60 years of age.

AGGLUTININ. An antibody that causes red blood cells to stick or clump together.

AGGRAVATED SEXUAL ABUSE. When an individual is forced to submit to sexual acts by use of physical force; threats of death, injury, or kidnapping; or substances that render that individual unconscious or impaired.

AGGREGATION. The blood cell clumping process that is measured in the platelet aggregation test.

AGITATION. Excessive restlessness or emotional disturbance that is often associated with anxiety or psychosis; common in middle-stage AD.

AGNOSIA. Loss of the ability to recognize objects by use of the physical senses.

AGONIST. Any drug that binds to a receptor (protein molecule embedded in a cell membrane) and activates the receptor to produce a biological response.

AGORAPHOBIA. Abnormal anxiety regarding public places or situations from which the patient may wish to flee or in which he or she would be helpless in the event of a panic attack.

AGRANULOCYTOSIS. An acute condition marked by severe depression of the bone marrow, which produces white blood cells, and by prostration, chills, swollen neck, and sore throat sometimes with local ulceration. Also called agranulocytic angina or granulocytopenia.

AIDS. Acquired immunodeficiency syndrome. A disease caused by infection with the human immunodeficiency virus (HIV). In people with this disease, the immune system breaks down, opening the door to other infections and some types of cancer.

AIDS DEMENTIA COMPLEX; ADC. Cognitive difficulties, confusion, and loss of muscular coordination caused by HIV-induced destruction of brain tissue.

AIDS-RELATED KAPOSI'S SARCOMA. A form of KS that emerged as one of the first illnesses associated with AIDS patients. Tumors usually appear on the upper body, the soft palate and gum areas, and, as the disease advances, in the lymph nodes, stomach, intestines, and lungs.

AKATHISIA. Agitated or restless movement, usually affecting the legs and accompanied by a sense of discomfort.

AKINESIA. A loss of the ability to move; freezing in place.

ALBERS-SCHÖNBERG DISEASE. The most common type of osteopetrosis; also called autosomal dominant osteopetrosis (ADO).

ALBINISM. A genetic disease characterized by the absence of the normal skin pigment, melanin.

ALBINO. A person or animal lacking normal coloring in the eyes, hair, and skin due to a hereditary

inability to produce the skin pigment melanin. The condition itself is called albinism.

ALBUMIN. A blood protein that is made in the liver and helps to regulate water movement in the body.

ALCOHOL POISONING. A potentially life-threatening condition caused by consuming large amounts of alcohol over a short period, negatively affecting heart rate, breathing, and the gag reflex.

ALCOHOL USE DISORDERS INVENTORY TEST (AUDIT). A test for alcohol use developed by the World Health Organization (WHO). Its 10 questions address three specific areas of drinking over a 12-month period: the amount and frequency of drinking, dependence upon alcohol, and problems that have been encountered due to drinking alcohol.

ALCOHOLIC ENERGY DRINK. Caffeinated alcoholic beverages; malt liquors that in addition to high alcohol content, have added caffeine and sometimes other stimulants.

ALDOLASE. An enzyme, found primarily in the muscle, that helps convert sugar into energy.

ALDOLASE B. Also called fructose 1-phosphate aldolase, this chemical is produced in the liver, kidneys, and brain. It is needed for the breakdown of fructose, a sugar found in fruits, vegetables, honey, and other sweeteners.

ALDOSTERONE. A hormone produced in the cortex of the adrenal gland that increases the reabsorption of sodium and water and the release of potassium in the kidneys.

ALDOSTERONISM. A disorder caused by excessive production of the hormone aldosterone, which is produced by a part of the adrenal glands called the adrenal cortex. Causes include a tumor of the adrenal gland (Conn's syndrome), or a disorder reducing the blood flow through the kidney. This leads to overproduction of renin and angiotensin, and in turn causes excessive aldosterone production. Symptoms include hypertension, impaired kidney function, thirst, and muscle weakness.

ALDOSTERONISM. A disorder caused by excessive production of the hormone aldosterone, which is produced by a part of the adrenal glands called the adrenal cortex. Causes include a tumor of the adrenal gland (Conn's syndrome), or a disorder reducing the blood flow through the kidney. This leads to overproduction of renin and angiotensin, and in turn causes excessive aldosterone production. Symptoms include hypertension, impaired kidney function, thirst, and muscle weakness.

ALENDRONATE. A non-hormonal drug used to treat osteoporosis in postmenopausal women.

ALEXANDER TECHNIQUE. A technique developed by Frederick Alexander that focuses on the variations in body posture, muscles, and breathing. Defects in these functions can lead to stress, nervous tension, or possible loss of function.

ALGAE. Plants that have one cell.

ALGINATE. Colloidal substances from marine brown algae, especially giant kelp, that are used for wound dressings.

ALKALINE. A solution is considered alkaline if it contains fewer hydrogen atoms than pure water.

ALKALINE PHOSPHATASE. An enzyme found throughout the body, primarily in liver, bone, placenta, and intestine.

ALKALOID. An organic compound found in plants; chemically it is a base and usually contains at least one nitrogen atom.

ALKALOSIS. A condition of the blood and other body fluids in which bicarbonate levels are higher than normal.

ALKYLATING AGENT. A chemical that alters the composition of the genetic material of rapidly dividing cells, such as cancer cells, causing selective cell death; used as a topical chemotherapeutic agent to treat CTCL.

ALLELE. Types of genes that occupy the same site on a chromosome.

ALLERGEN. A substance that provokes an allergic response.

ALLERGENIC. A substance capable of causing an allergic reaction.

ALLERGIC REACTION. An immune system reaction to a substance in the environment; symptoms include rash, inflammation, sneezing, itchy watery eyes, runny nose, or skin irritations.

ALLERGIC RHINITIS. Inflammation of the mucous membranes of the nose and eyes in response to an allergen; hay fever is seasonal allergic rhinitis.

ALLERGY. An immune system reaction to a substance in the environment; symptoms include rash, inflammation, sneezing, itchy watery eyes, runny nose, or skin irritations.

WWW.BOOKBAZ.IR

ALLEVIATE. To make something easier to be endured.

ALLOGENEIC. A transplant where the donated material comes from a genetically different (although often related) individual than the recipient.

ALLOGRAFT. Tissue that is taken from one person's body and grafted to another person.

ALLOPATHIC. Pertaining to conventional medical treatment of disease symptoms that uses substances or techniques to oppose or suppress the symptoms.

ALLOPATHY. Conventional medical treatment of disease symptoms that uses substances or techniques to oppose or suppress the symptoms.

ALLOPURINOL. A drug that corrects hyperuricemia by inhibiting urate production.

ALOE VERA. An extract from the plant *Aloe barbadensis* that is used in skin creams and for treating burns.

ALOPECIA. Hair loss or baldness.

ALPHA 1-ANTITRYPSIN DEFICIENCY. A genetic disorder characterized by insufficient production of alpha 1-antitrypsin (A1AT), a substance that protects the elasticity of lung tissue. Patients with insufficient A1AT are at high risk of developing emphysema, particularly if they are smokers.

ALPHA BLOCKERS. Medications that bind alpha adrenergic receptors and decrease the workload of the heart and lower blood pressure. They are commonly used to treat hypertension, peripheral vascular disease, and hyperplasia.

ALPHA-FETOPROTEIN (AFP). A protein in blood serum that is found in abnormally high concentrations in most patients with primary liver cancer.

ALPHA-FETOPROTEIN ANALYSIS. A blood test that can be done after the sixteenth week of pregnancy to evaluate the possibility of spina bifida and other birth defects in the fetus.

ALPHA FETOPROTEIN SCREEN. A test that measures the level of alpha fetoprotein, a substance produced by a fetus with birth defects, in the mother's blood.

ALPHA-2 AGONIST. A class of drugs that bind to and stimulate alpha-2 adrenergic receptors, causing responses similar to those of adrenaline and noradrenaline, by inhibiting aqueous humor production.

ALPHA-INTERFERON. A natural body substance that now can be made in large quantities and is an effective treatment for some types of viral inflammatory disease, including hepatitis C.

ALPHA-LINOLENIC ACID (ALA). A polyunsaturated omega-3 fatty acid found primarily in seed oils (canola oil, flaxseed oil, and walnut oil), purslane and other broad-leaved plants, and soybeans. ALA is thought to lower the risk of cardiovascular disease.

ALPHA-THALASSEMIA. An inherited disorder that interferes with the normal production of hemoglobin.

ALPHA-TOCOPHEROL. The most biologically active form of vitamin E.

ALPROSTADIL. A smooth muscle relaxant sometimes injected into the penis or applied to the urethral opening to treat impotence.

ALTER. An alternate or secondary personality in a patient with DID.

ALTERNATING CURRENT (AC). An electric current in which the flow of the electric charge periodically reverses direction. AC is the form in which electricity is usually delivered to homes. The usual household wall outlet (120 volts) provides a current with 120 reversals of the direction of flow occurring each second and is termed 60-cycle alternating current.

ALTERNATIVE MEDICINE. Any nonconventional treatment or substance that is used in place of mainstream medical or surgical treatment.

ALTERNATIVE THERAPY. A therapy is generally called alternative when it is used instead of conventional treatments.

ALVARADO SCORE. A ten-point scoring system used by doctors to evaluate the likelihood that a patient has acute appendicitis.

ALVEOLI. Tiny air sacs in the lungs where gas exchange takes place between alveolar air and pulmonary blood within the capillaries

ALYKYLATING DRUG. A drug that kills cells by directly damaging DNA.

ALZHEIMER'S DISEASE. A progressive, neurodegenerative disease characterized by loss of function and death of nerve cells in several areas of the brain, leading to loss of mental functions, such as memory and learning. Alzheimer's disease is the most common cause of dementia.

AMALGAM. A mixture (alloy) of silver and several other metals, used by dentists to make fillings for cavities.

AMBIENT. Surrounding.

AMBLYOPIA. Decreased visual acuity, usually in one eye, in the absence of any structural abnormality in the eye.

AMBULATION. Moving from place to place.

AMBULATORY MONITORING. ECG recording over a prolonged period during which the patient can move around.

AMBULATORY MONITORS. Small portable electrocardiograph machines that record the heart's rhythm. Ambulatory monitors include the Holter monitor, loop recorder, and transtelephonic transmitter. Each type of monitor has specific features related to the length of recording time and the ability to send the recordings over the phone.

AMEBIASIS. An infection caused by an ameba, which is a type of protozoan.

AMEBOMA. A mass of tissue that can develop on the wall of the colon in response to amebic infection.

AMENORRHEA. Abnormal cessation of menstruation.

AMINO ACID. Organic compounds that form the building blocks of protein. There are 20 types of amino acids (eight are "essential amino acids" which the body cannot make and must therefore be obtained from food).

AMINOACIDURIA. The abnormal presence of amino acids in the urine.

AMNESIA. A general medical term for loss of memory that is not due to ordinary forgetfulness. Amnesia can be caused by head injuries, brain disease, or epilepsy, as well as by dissociation.

AMNESIC. Relating to amnesia, the loss of memory.

AMNIOCENTESIS. A procedure performed at 16–18 weeks of pregnancy in which a needle is inserted through a woman's abdomen into her uterus to draw out a small sample of the amniotic fluid from around the baby. Either the fluid itself or cells from the fluid can be used for a variety of tests to obtain information about genetic disorders and other medical conditions in the fetus.

AMNIOTIC BAND. An abnormal condition of fetal development in which fibrous bands of tissue develop out of the amniotic sac. The bands encircle and constrict parts of the baby's body, interfering with normal development and sometimes causing congenital amputation.

AMNIOTIC FLUID. The liquid in the placental sac that cushions the fetus and regulates temperature in the placental environment. Amniotic fluid also contains fetal cells.

AMNIOTIC MEMBRANE. The thin tissue that creates the walls of the amniotic sac.

AMNIOTIC SAC. The membranous sac that surrounds the embryo and fills with watery fluid as pregnancy advances.

AMOEBA. A type of protozoa (one-celled animal) that can move or change its shape by extending projections of its cytoplasm.

AMPERAGE. A measurement of the amount of electric charge passing a given point per unit time. One ampere represents about 6.241×10^{18} electrons passing a given point in a wire in one second of time.

AMPHOTERICIN B. An antibiotic used to treat mucormycosis and other severe fungal infections.

AMPLIFICATION. A process by which something is made larger. In clotting, only a very few chemicals are released by the initial injury; they result in a cascade of chemical reactions which produce increasingly larger quantities of different chemicals, resulting in an appropriately-sized, strong fibrin clot.

AMPULLA OF VATER. The widened portion of the duct through which bile and pancreatic juices enter the intestine. Ampulla is a Latin word for a bottle with a narrow neck that opens into a wide body.

AMPUTATION. Surgical removal of a limb.

AMYGDALA. An almond-shaped brain structure of the limbic system that is activated in stressful situations and triggers fear.

AMYLASE. A digestive enzyme made primarily by the pancreas and salivary glands.

AMYLOID. A waxy translucent substance composed mostly of protein, that forms plaques (abnormal deposits) in the brain.

AMYLOIDOSIS. Accumulation of amyloid deposits in various organs and tissues in the body such that normal functioning of an organ is compromised.

AMYLOPHAGIA. The compulsive eating of purified starch, typically cornstarch or laundry starch.

ANABOLIC. Causing muscle and bone growth and a shift from fat to muscle in the body.

ANABOLIC STEROID. Drugs derived from the male sex hormones that increase the rate of tissue growth.

WWW.BOOKBAZ.IR

They are best known for increasing the rate of muscle development.

ANAEROBE. A type of bacterium that does not require air or oxygen to live. Anaerobic bacteria are frequent causes of lung abscess.

ANAEROBIC. Living and growing in the absence of oxygen.

ANAEROBIC BACTERIA. Bacteria that cannot grow or reproduce in the presence of oxygen.

ANAGRELIDE. An orphan drug that is approved for treating PV patients on an investigational basis. Anagrelide works by controlling the level of platelets in the blood.

ANAL FISSURE. An ulcer on the margin of the anus.

ANAL SPHINCTER MUSCLES. Muscles that control the opening and closing of the anus.

ANALGESIA. A state of insensitivity to pain even though the person remains fully conscious.

ANALGESIC. A medication that relieves pain without causing loss of consciousness. Over-the-counter analgesics include aspirin and NSAIDs.

ANALOGUE. A drug that is similar to the drug from which it is derived.

ANALYSAND. A person undergoing psychoanalysis.

ANAPHYLACTIC SHOCK. A severe allergic reaction that causes blood pressure drop, racing heart, swelling of the airway, rash, and possibly convulsions.

ANAPHYLAXIS. A severe allergic reaction that causes blood pressure drop, racing heart, swelling of the airway, rash, and possibly convulsions.

ANASTOMOSIS. A type of surgical procedure in which the surgeon joins together two parts of a hollow organ (such as a blood vessel or portion of the intestine) after a diseased or damaged section has been removed.

ANATOMIC. Related to the physical structure of an organ or organism.

ANATOMIST. A biomedical professional who specializes in teaching anatomy or performing anatomical studies and research.

ANATOMY. The science of the body structure of an organism and its parts.

ANDROGENIC. Causing testosterone-like, masculinizing effects.

ANDROGENS. Male sex hormones produced by the adrenal glands and testes, the male sex glands.

ANDROGYNY. The condition of having the characteristics of both a man and a woman, or not being clearly identified as male or female. The English word is a combination of two Greek words meaning "(adult) man" and "woman." Androgyny may refer to a person's physical characteristics, psychological characteristics, or behavior.

ANDROPAUSE. A gradual, highly variable decline in testosterone and other male hormones and associated symptoms; occurring during and after middle age.

ANDROSTENEDIONE. Also called "andro," this hormone occurs naturally during the making of testosterone and estrogen.

ANEMIA. A condition in which there is low iron in the blood due to a deficiency of red blood cells.

ANEMIA OF CHRONIC DISEASE (ACD). A blood disorder that results from a medical condition that affects the production and lifespan of red blood cells.

ANENCEPHALY. A hereditary defect resulting in the partial to complete absence of a brain and spinal cord. It is fatal.

ANESTHESIA. A combination of drugs administered by a variety of techniques by trained professionals that provide sedation, amnesia, analgesia, and immobility adequate for the accomplishment of the surgical procedure with minimal discomfort to the patient.

ANESTHESIOLOGIST. A medical specialist who administers an anesthetic to a patient before the person is treated.

ANESTHETIC. Medicine that causes a loss of feeling, especially pain. Some anesthetics also cause a loss of consciousness.

ANEURYSM. A weak point in a blood vessel where the pressure of the blood causes the vessel wall to bulge outwards.

ANGINA. Also called angina pectoris, chest pain or discomfort that occurs when diseased blood vessels restrict blood flow to the heart.

ANGINA PECTORIS. Chest pain or discomfort that occurs when diseased blood vessels restrict blood flow to the heart.

ANGIOEDEMA. Severe, noninflammatory swelling of the skin, organs, and brain, possibly accompanied by fever and muscle pain.

ANGIOGENESIS. Severe, noninflammatory swelling of the skin, organs, and brain, possibly accompanied by fever and muscle pain.

ANGIOGRAM. X ray of a blood vessel after special x-ray dye has been injected into it.

ANGIOGRAPHY. Any of the different methods for investigating the condition of blood vessels, usually via a combination of radiological imaging and injections of chemical tracing and contrasting agents.

ANGIOID STREAKS. Gray, orange, or red wavy, branching lines in Bruch's membrane.

ANGIOMA. A tumor (such as a hemangioma or lymphangioma) that mainly consists of blood vessels or lymphatic vessels.

ANGIOPLASTY. A procedure in which a balloon catheter is used to mechanically dilate the affected area of a diseased artery and enlarge the constricted or narrowed segment.

ANGIOSPASM. Spasmodic contraction of a blood vessel with increase in blood pressure.

ANGIOTENSIN-CONVERTING ENZYME (ACE) INHIBITOR. A drug that relaxes blood vessel walls and lowers blood pressure.

ANION. An ion carrying a negative charge owing to a surplus of electrons. Anions in the body include bicarbonate, chloride, phosphate, sulfate, certain organic acids, and certain protein compounds.

ANISOMETROPIA. An eye condition in which there is an inequality of vision between the two eyes. There may be unequal amounts of nearsightedness, farsightedness, or astigmatism, so that one eye will be in focus while the other is not.

ANKLE-BRACHIAL INDEX (ABI) TEST. A means of checking the blood pressure in the arms and ankles using a regular blood pressure cuff and a special ultrasound stethoscope (Doppler). The pressure in the ankle is compared to the pressure in the arm.

ANKYLOSING. When bones of a joint are fused, stiff, or rigid.

ANKYLOSING SPONDYLITIS. A form of inflammatory arthritis in which the bones in the spine and pelvis gradually fuse when inflamed connective tissue is replaced by bone.

ANODE. The positive electrode to which an electromagnetic current flows.

ANOGENITORECTAL SYNDROME. Another name for third-stage LGV.

ANOMIC APHASIA. A condition characterized by either partial or total loss of the ability to recall the names of persons or things as a result of a stroke, head injury, brain tumor, or infection.

ANOREXIA NERVOSA. A serious eating disorder characterized by extreme weight loss, distorted body image, and fear of gaining weight.

ANORGASMIA. A sexual dysfunction characterized by the inability to achieve orgasm.

ANOVULATION. The absence of ovulation.

ANOVULATORY BLEEDING. Bleeding without release of an egg from an ovary.

ANOXEMIA. An extreme lack of oxygen in the blood.

ANOXIA. An absence of oxygen.

ANTACIDS. Substances that counteract or neutralize acidity. They act promptly and have short durations of actions.

ANTAGONIST. A drug that blocks the action of a substance, such as an opiate, by binding to its receptor.

ANTEPARTUM. This refers to the time period of the woman's pregnancy from conception and onset of labor.

ANTERIOR CERVICAL DISKECTOMY AND FUSION (ACDF). Disc removal and spinal fusion performed through the front of the neck.

ANTERIOR LUMBAR INTERBODY FUSION (ALIF). Spinal fusion performed through the left side of the abdomen following disk removal.

ANTEROGRADE. Memory loss for information/events occurring after the onset of the amnestic disorder.

ANTHELMINTHIC. A type of medication that is given to destroy or eliminate parasitic worms.

ANTHRAX. An infectious disease caused by a type of bacterium. The disease can be passed from animals to people and usually is fatal. Symptoms include sores on the skin.

ANTHROPOLOGY. The study of the origins, biological characteristics, beliefs, and social customs of human beings.

ANTIANDROGEN. A substance that blocks the action of androgens, the hormones responsible for male characteristics.

WWW.BOOKBAZ.IR

ANTIARRHYTHMIC. Medication used to treat abnormal heart rhythms.

ANTIBIOTIC. A medication that is designed to kill or weaken bacteria.

ANTIBIOTIC RESISTANCE. The ability of infectious agents to change their biochemistry in such a way as to make an antibiotic no longer effective.

ANTIBODY. A specific protein produced by the immune system in response to a specific foreign protein or particle called an antigen.

ANTICHOLINERGIC. Any drug that blocks the neurotransmitter acetylcholine in the nervous system. Acetylcholine is responsible for the involuntary contraction of smooth muscle in the gastrointestinal tract; thus a drug that blocks acetylcholine assists in suppressing intestinal cramping and nausea.

ANTICOAGULANT. Drug used to prevent clot formation or to prevent a clot that has formed from enlarging. Also called blood thinners, anticoagulant drugs inhibit clot formation by blocking the action of clotting factors or platelets. Anticoagulant drugs fall into three groups: inhibitors of clotting factor synthesis, inhibitors of thrombin, and antiplatelet drugs.

ANTICONVULSANT. Group of medications used in the treatment of seizures.

ANTIDEPRESSANT. A medication used to relieve the symptoms of clinical depression.

ANTIDIURETIC HORMONE (ADH); VASOPRESSIN. A substance stored in the pituitary gland and released at night to diminish the formation of urine.

ANTIDOTE. A remedy to counteract unwanted effects from medications or poisons.

ANTIEMETIC. A type of medication given to prevent or reduce nausea and vomiting.

ANTIGEN. A foreign protein or particle that causes the body to produce specific antibodies that bind to it.

ANTIGEN PRESENTING CELL. A cell of the immune system that ingests antigens and exposes them to cells of the immune system in a way that activates the cells to seek out and destroy any other cells displaying that antigen.

ANTIHISTAMINE. A drug that inhibits the actions of histamine. Histamine causes dilatation of capillaries, contraction of smooth muscle, and stimulation of gastric acid secretion.

ANTI-INFLAMMATORY. Medicine used to relieve swelling, pain, and other symptoms of inflammation.

ANTIMETABOLITE. An immunosuppressive drug that works by interfering with a cell's use of a metabolite (a byproduct of normal metabolism). Antimetabolites thus inhibit the growth and division of cells.

ANTIMICROBIAL. A substance or action that kills or inhibits the growth of microorganisms.

ANTIMICROBIAL AGENT. A substance that kills microorganisms such as bacteria or mold, or stops them from growing and causing disease.

ANTIMICROBIAL RESISTANCE. Drug resistance in pathogens, including bacteria, viruses, fungi, and parasites.

ANTIMOTILITY MEDICATIONS. Medications such as loperamide (Imodium), dephenoxylate (Lomotil), or medications containing codeine or narcotics which decrease the ability of the intestine to contract. This can worsen the condition of a patient with dysentery or colitis.

ANTIMYOCARDIAL ANTIBODY. An autoantibody that attacks a person's own heart muscle, or myocardium.

ANTINEOPLASTIC. A drug used to inhibit the growth and spread of cancerous cells.

ANTINUCLEAR ANTIBODIES (ANA). Abnormal antibodies against cell nuclei in the blood of people with autoimmune diseases such as rheumatoid arthritis.

ANTINUCLEAR ANTIBODY (ANA) TEST. A test often used to look for autoantibodies that react against components of the nucleus of the body's cells. Many people with lupus test positive for ANA.

ANTIOXIDANT. A substance that prevents the destructive effects of oxidative chemicals in the body.

ANTIPLATELET. A drug that reduces or destroys the activity of blood-clotting platelets; used to prevent strokes.

ANTIPLATELET DRUG. Drug that inhibits platelets from aggregating to form a plug. They are used to prevent clotting and alter the natural course of atherosclerosis.

ANTIPSYCHOTICS. Drugs used to treat psychotic conditions such as schizophrenia or psychosis. These medications are powerful tranquilizers that all have sedating and calming effects, but their major effect is to reduce psychotic thinking and behavior.

ANTIPYRETIC. A drug that lowers fever, like aspirin or acetaminophen.

ANTIRETROVIRAL THERAPY (ART). The use of one or more drugs to prevent, limit, or treat HIV/AIDS.

ANTISEPTIC. Inhibits the growth of microorganisms.

ANTISOCIAL PERSONALITY. A personality characterized by attitudes and behaviors at odds with society's customs and moral standards, including illegal acts.

ANTITHROMBOTIC. Preventing clot formation.

ANTITOXIN. A substance that inactivates a poison (e.g., toxin) and protects the body from being injured by it.

ANTITUSSIVES. Drugs used to suppress coughing.

ANTIVIRAL. A drug that prevents viruses from replicating and therefore spreading infection

ANTRECTOMY. The operation of opening an antrum (cavity) for drainage.

ANUS. The opening at the end of the intestine through which solid waste (stool) passes as it leaves the body.

ANXIETY. Worry or tension in response to real or imagined stress or danger. Physical reactions such as fast pulse, sweating, trembling, fatigue, and weakness may accompany anxiety.

ANXIETY DISORDERS. A group of psychological disorders that are all characterized by abnormal fear and/or excessive anxiety.

ANXIOLYTIC. A type of medication that helps to relieve anxiety.

AORTA. The largest artery in the body, which moves blood from the left ventricle to the rest of the body.

AORTIC ANEURYSMS. Occurs when an area in the aorta (the main artery of the heart) is weakened and bulges like a balloon.

AORTIC DISSECTION. A tear in the aorta (the main blood vessel carrying blood away from the heart) that allows blood to flow between layers of the aorta, eventually causing it to fail.

AORTIC STENOSIS. A stiffening of the artery which carries blood from the heart to the body.

AORTIC VALVE. The valve between the left ventricle of the heart and the aorta.

APANA. Life sustaining energy centered in the larger intestine; the fifth of the five airs of Ayurvedic philosophy; the life force governing expulsion activity.

APHAKIA. Absence of the lens of the eye.

APHASIA. Loss of previously acquired ability to speak, or to understand written or spoken language.

APHERESIS. A procedure in which whole blood is withdrawn from a donor, a specific blood component is separated and collected, and the remainder is reinfused into the patient.

APHTHOUS STOMATITIS. A specific type of stomatitis presenting with shallow, painful ulcers. Also known as *canker sores*.

APICAL. Rounded end of the root of a tooth that is embedded in hard tissue (bone); toward the apex of the root.

APICOECTOMY. Also called root resectioning. The root tip of a tooth is accessed in the bone and a small amount is shaved away. The diseased tissue is removed and a filling is placed to reseal the canal.

APLASTIC. Exhibiting incomplete or faulty development.

APLASTIC ANEMIA. A disorder in which the body produces inadequate amounts of red blood cells and hemoglobin due to underdeveloped or missing bone marrow.

APNEA. A period of no breathing, sometimes sudden, sometimes prolonged.

APOLIPOPROTEIN E (APOE). A protein that transports cholesterol throughout the body. One form of this protein, APOE e4, is associated with a 60% risk of late-onset AD.

APOPTOSIS. Cell death.

APPENDECTOMY. Surgical removal of the appendix.

APPENDICITIS. Condition characterized by the rapid inflammation of the appendix, a part of the intestine.

APPENDIX. A portion of intestine attached to the cecum.

APPERCEPTION. The process of understanding through linkage with previous experience.

APPETITE SUPPRESSANT. A drug that reduces appetite.

APRAXIA. Impairment of the ability to make purposeful movements, but not paralysis or loss of sensation.

WWW.BOOKBAZ.IR

AQUEOUS HUMOR. A transparent liquid, contained within the eye, that is composed of water, sugars, vitamins, proteins, and other nutrients.

ARACHNODACTYLY. A condition characterized by abnormally long and slender fingers and toes.

ARACHNOID. One of the membranes that sheathes the spinal cord and brain; the arachnoid is the second-layer membrane.

ARACHNOID MATER. One of three membranes that encase the brain and spinal cord. The arachnoid mater is the middle membrane.

ARBOVIRUS. A virus that is transmitted to a host by an insect or other arthropod vector.

ARC FLASH. A type of electrical explosion resulting from electrical breakdown of the gases in air, which normally does not conduct electricity. Arc flashes can occur where there is sufficient voltage in an electrical system and a path to the ground or to lower voltage.

AREA POSTREMA. A small tongue-shaped structure that lies on the floor of the fourth ventricle of the brain.

AREOLA. The pigmented, circular area surrounding the nipple of each breast.

ARGON. A colorless, odorless gas.

AROMATASE. An enzyme that converts an androgen to an estrogen; aromatase inhibitors are used to treat estrogen receptor-positive breast cancer.

AROMATASE INHIBITOR. A medication for preventing or treating breast cancer in postmenopausal women by inhibiting the body's production of estrogen.

AROMATHERAPY. The therapeutic use of plant-derived, aromatic essential oils to promote physical and psychological well-being.

ARREST. A sudden stopping of the function of a body organ, such as no breathing (respiratory arrest) or no beating of the heart (cardiac arrest).

ARRHYTHMIA. Abnormal heartbeat.

ARTEMINISININS. A family of antimalarial products derived from an ancient Chinese herbal remedy. Two of the most popular varieties are artemether and artesunate, used mainly in southeast Asia in combination with mefloquine.

ARTERIAL BLOOD GASES TEST. A test to analyze blood for oxygen, carbon dioxide, and bicarbonate content, as well as blood pH (acidity level). Used to test the effectiveness of respiration.

ARTERIAL EMBOLISM. A blood clot arising from another location that blocks an artery.

ARTERIOGRAM. A diagnostic test that involves viewing the arteries and/or attached organs by injecting a contrast medium, or dye, into the artery and taking an x ray.

ARTERIOGRAM. An x-ray picture of an artery achieved by injecting an opaque dye with a needle or tube into the affected artery.

ARTERIOGRAPHY. A medical test in which an x-ray visible dye is injected into blood vessels. This dye allows the blood vessels to be imaged with x rays.

ARTERIOLE. The smallest type of artery.

ARTERIOLES. Small blood vessels that carry arterial (oxygenated) blood.

ARTERIOSCLEROSIS. A chronic condition characterized by thickening and hardening of the arteries and the build-up of plaque on the arterial walls. Arteriosclerosis can slow or impair blood circulation.

ARTERIOVENOUS MALFORMATION. An abnormal tangle of arteries and veins in which the arteries feed directly into the veins without a normal intervening capillary bed.

ARTERITIS. Inflammation of an artery.

ARTERY. A blood vessel that carries blood from the heart to the body's tissues.

ARTHEROSCLEROTIC PLAQUE. A deposit of fatty and calcium substances that accumulate in the lining of the artery wall, restricting blood flow.

ARTHRALGIA. Sharp, severe pain, extending along a nerve or group of nerves, experienced in a joint and/or joints.

ARTHRITIS. Inflammation of a joint or joints that may lead to changes in the joint's structure. It causes pain and swelling.

ARTHROCENTESIS. A procedure in which the doctor inserts a needle into the patient's joint to withdraw fluid for diagnostic testing or to drain infected fluid from the joint.

ARTHROCHALASIA. Excessive looseness of the joints.

ARTHRODESIS. A surgical procedure sometimes used to treat younger patients with hip problems, in which the head of the femur is fused directly to the acetabulum.

ARTHRODESIS. Inflammation of a joint or joints that may lead to changes in the joint's structure. It causes pain and swelling.

ARTHROGRAM. A test done by injecting dye into the shoulder joint and then taking x rays. Areas where the dye leaks out indicate a tear in the tendons.

ARTHROGRAPHY. An imaging technique that is sometimes used to evaluate TMJ associated with internal derangement.

ARTHROPLASTY. The medical term for surgical replacement of a joint. Arthroplasty can refer to knee as well as hip replacement.

ARTHROPOD. An insect or other invertebrate (lacking a backbone) that has an external skeleton (exoskeleton), a segmented body, and jointed appendage.

ARTHROSCLEROSIS. A condition where fatty deposits cause the arteries to narrow.

ARTHROSCOPE. A pencil-sized, fiber-optic instrument fitted with a lens, light source, and camera, used for detailed examination of joints.

ARTHROSCOPIC KNEE SURGERY. Surgery performed to examine or repair tissues inside the knee joint through a special scope (arthroscope).

ARTHROSCOPY. Examination of a joint with an arthroscope or joint surgery using an arthroscope.

ARTICULAR BONES. Two or more bones connected with each other via a joint.

ARTICULAR CAPSULE. An envelope of tissue that surrounds a free moving joint, composed of an external layer of white fibrous tissue and an external synovial membrane that secretes a lubricant into the joint.

ARTICULATION. The ability to pronounce a word correctly. A lisp is an example of an articulation problem.

ARTIFICIAL AIRWAY. A passage for respiration that is created and maintained by a device, such as tubing. Artificial airways are usually established for patients who are at risk of having their own natural airways collapse because of trauma or another medical condition.

ASANA. A position or stance in yoga.

ASBESTOS. A naturally occurring mineral, utilized worldwide for its durability and heat resistant qualities. Extremely fibrous in nature, asbestos particles can easily enter the respiratory system and damage sensitive tissue. This damage can result in asbestosis, mesothelioma, and lung cancer.

ASCITES. Accumulation of fluid in the abdomen.

ASCORBIC ACID. Another term for vitamin C, a nutrient found in fresh fruits and vegetables. Good sources of vitamin C in the diet are citrus fruits like oranges, lemons, limes, and grapefruits, berries, tomatoes, green peppers, cabbage, broccoli, and spinach.

ASEPTIC. Sterile; containing no microorganisms, especially no bacteria.

ASEPTIC MENINGITIS. A term that is sometimes used for meningitis that is not caused by bacteria.

ASEPTIC TECHNIQUE. Practices performed before, during, and after a clinical procedure to prevent or reduce contamination and postprocedural infection.

ASEXUALITY. Lack of interest in sexual activity or lack of sexual attraction to others. It should not be confused with abstinence, which is a behavioral choice.

ASHERMAN'S SYNDROME. The cessation of menstruation and/or infertility caused by intrauterine adhesions.

ASPERGER SYNDROME. Children who have autistic behavior but no problems with language and no clinically significant cognitive delay.

ASPERGILLOMA. A ball or mass made of *Aspergillus* fungi that can form in the lungs of patients with suppressed immune systems.

ASPERGILLOSIS. A lung infection caused by the mold *Aspergillus fumigatus*.

ASPHYXIA. Lack of oxygen. In the case of cerebral palsy, lack of oxygen to the brain.

ASPHYXIATION. Oxygen starvation of tissues. Chemicals such as carbon monoxide prevent the blood from carrying sufficient oxygen to the brain and other organs. As a result, the person may lose consciousness, stop breathing, and die without artificial respiration (assisted breathing) and other means of elevating the blood oxygen level.

ASPIRATE. A procedure to withdraw fluid and cells from the body.

ASPIRATION. The process in which solid food, liquids, or secretions that normally are swallowed are, instead, breathed into the lungs.

ASPIRATOR. A medical instrument that uses suction to withdraw fluids from the lungs, digestive tract, or other parts of the body for laboratory testing.

WWW.BOOKBAZ.IR

ASPIRIN. A commonly used drug for pain relief and to decrease fever.

ASSAY. An analysis of the chemical composition or strength of a substance.

ASSISTED SUICIDE. Voluntarily ending one's life with the help of a physician, relative, or friend, usually in the face of terminal illness.

ASTHENIA. Muscle weakness.

ASTHMA. A disease in which the air passages of the lungs become inflamed and narrowed.

ASTIGMATISM. Asymmetric vision defects due to irregularities in the cornea.

ASYMMETRIC. Not occurring equally on both sides of the body.

ASYMPTOMATIC. Persons who carry a disease but who do not exhibit symptoms of the disease are said to be asymptomatic.

ATAXIA. Loss of coordination of muscular movement.

ATAXIA-TELANGIECTASIA (A-T). Also called Louis-Bar syndrome, a rare neurodegenerative disease that is inherited and can cause severe disability; the term *ataxia* refers to poor coordination and *telangiectasia* relates to small dilated blood vessels.

ATELECTASIS. Partial or complete collapse of the lung, usually due to a blockage of the air passages with fluid, mucus, or infection.

ATHERECTOMY. A nonsurgical technique for treating diseased arteries with a rotating device that cuts or shaves away obstructing material inside the artery.

ATHEROSCLEROSIS. A chronic condition characterized by thickening and hardening of the arteries and the buildup of plaque on the arterial walls. Atherosclerosis can slow or impair blood circulation.

ATHEROSCLEROTIC DISEASE. A chronic condition characterized by thickening and hardening of the arteries and the buildup of plaque on the arterial walls. Atherosclerosis can slow or impair blood circulation.

ATHEROSCLEROTIC PLAQUE. A deposit of fat and other substances that accumulate in the lining of the artery wall.

ATHETOSIS. A condition marked by slow, writhing, involuntary muscle movements.

ATMOSPHERE. A measurement of pressure. One atmosphere equals the pressure of air at sea level (14.7 pounds per square inch [psi]).

ATOMIZER. The battery-powered electric coil inside an e-cigarette that vaporizes the e-liquid. It contains a wick that draws in the e-liquid for vaporization.

ATOPIC DERMATITIS. Eczema; a skin condition resulting from exposure to airborne, food, or drug allergens.

ATOPY. Genetic susceptibility to allergies and asthma.

ATP. Adenosine triphosphate; a nucleotide with three phosphate groups that supplies cellular energy by undergoing enzymatic hydrolysis to adenosine diphosphate (ADP) and adenosine monophosphate (AMP).

ATRESIA. Failure to develop; complete absence.

ATRIA. The two small upper chambers of the heart that receive blood from the lungs and the body.

ATRIAL. Having to do with the upper chambers of the heart.

ATRIAL FIBRILLATION. A condition in which the upper chamber of the heart quivers instead of pumping in an organized way.

ATRIAL FLUTTER. A rapid pulsation of the upper chambers of the heart that interferes with normal heart function. Atrial flutter is usually more organized and regular than atrial fibrillation, although it often converts to atrial fibrillation. Atrial flutter occurs most often in people with heart disease and in the first week after heart surgery.

ATRIOVENTRICULAR NODE (AV NODE). Highly specialized area of the heart muscle that transmits electrical impulses.

ATRIUM. One of the two upper chambers of the heart.

ATROPHIC. A wasting or decrease in size of a muscle or other tissue.

ATROPHY. A wasting or decrease in size of a muscle or other tissue.

ATROPINE. A poisonous alkaloid obtained from belladonna or related plants, used medically to dilate the pupils of the eyes and to stop spasms.

ATTENTION DEFICIT DISORDER (ADD). Disorder characterized by a short attention span, impulsivity, and in some cases hyperactivity.

ATTENTION DEFICIT HYPERACTIVITY DISORDER (ADHD). A learning and behavioral disorder characterized by difficulty in sustaining attention, impulsive behavior, and excessive activity.

ATTENUATED. Alive but weakened; an attenuated microorganism can no longer produce disease.

ATTUNEMENT. Life energy teaching given by Reiki master to a student.

AUDIOGRAM. A chart or graph of the results of a hearing test conducted with audiographic equipment. The chart reflects the softest (lowest volume) sounds that can be heard at various frequencies or pitches.

AUDIOLOGIST. A person with a degree and/or certification in the areas of identification and measurement of hearing impairments and rehabilitation of those with hearing problems.

AUDITORY. Relating to the sense of the organs of hearing.

AUDITORY NERVE. The nerve that carries electrical signals from the cochlea to the brain.

AURA. A subjective sensation or motor phenomenon that precedes and indicates the onset of a neurological episode, such as a migraine or an epileptic seizure.

AURICLE. The external structure of the ear.

AURICULAR ACUPUNCTURE. Acupuncture using only points found on the ears.

AUSCULTATION. The process of listening to sounds that are produced in the body. Direct auscultation uses the ear alone, such as when listening to the grating of a moving joint. Indirect auscultation involves the use of a stethoscope to amplify the sounds from within the body, like a heartbeat.

AUTISM. A severe developmental disorder that usually begins before three years of age and affects a child's social as well as intellectual development.

AUTISTIC PSYCHOPATHY. Hans Asperger's original name for Asperger syndrome. It is still used occasionally as a synonym for the disorder.

AUTOANTIBODY. An antibody that attacks the body's own cells or tissues.

AUTOGENIC TRAINING. A form of self-hypnosis developed in Germany that appears to be beneficial for migraine sufferers.

AUTOGRAFT. Tissue that is taken from one part of a person's body and transplanted to a different part of the same person.

AUTOIMMUNE. Inappropriate immune system responses to the body's own proteins, cells, or tissues.

AUTOIMMUNE DISORDER. A disorder in which the body's antibodies mistake the body's own tissues for foreign invaders. The immune system then attacks and causes damage to these tissues.

AUTOIMMUNITY. A condition in which the body's immune system produces antibodies in response to its own tissues or blood components instead of foreign particles or microorganisms.

AUTOINFECTION. An infection caused by a disease agent that is already present in the body.

AUTOINTOXICATION. Self-poisoning by toxic products formed within the body during intestinal digestion. This term was coined around 1885 as part of a theory that regarded intestinal function as a central aspect of health.

AUTOLOGOUS. Derived from the same individual's body.

AUTOLOGOUS BLOOD. The patient's own blood is drawn and set aside for use during surgery in case a transfusion is needed.

AUTOLOGOUS DONATION. The patient's own blood is drawn and set aside for use during surgery in case a transfusion is needed.

AUTOLOGOUS TRANSPLANTATION. A procedure wherein the person donates blood or tissue to themselves.

AUTOLYTIC. Self-digestion; breakdown of tissue by the body's own enzymes.

AUTOMATIC EXTERNAL DEFIBRILLATOR (AED). An electronic device for restoring regular heart rhythm.

AUTOMATIC THOUGHTS. Thoughts that automatically come to mind when a particular situation occurs. Cognitive-behavioral therapy seeks to challenge automatic thoughts.

AUTOMATISM. An automatic action or reflex.

AUTOMATISMS. Movements during a seizure that are semi-purposeful but involuntary.

AUTONOMIC. Refers to peripheral nerves that carry signals from the brain and that control involuntary actions in the body, such as the beating of the heart.

WWW.BOOKBAZ.IR

AUTONOMIC NERVOUS SYSTEM. The part of the nervous system that controls so-called involuntary functions such as heart rate, salivary gland secretion, respiratory function, and pupil dilation.

AUTOPSY. The examination of a body after death to determine the cause of death.

AUTOSOMAL. Relating to any chromosome besides the X and Y sex chromosomes. Human cells contain 22 pairs of autosomes and one pair of sex chromosomes.

AUTOSOMAL CHROMOSOME. Relating to any chromosome besides the X and Y sex chromosomes. Human cells contain 22 pairs of autosomes and one pair of sex chromosomes.

AUTOSOMAL DISEASE. A disease caused by a gene mutation located on a chromosome other than a sex chromosome.

AUTOSOMAL DOMINANCE. A pattern of inheritance in which the dominant gene on any non-sex chromosome carries the defect.

AUTOSOMAL GENE. A gene found on one of the 22 autosomal chromosome pairs; i.e., not on a sex (X or Y) chromosome.

AUTOSOMAL RECESSIVE. A pattern of inheritance in which both copies of an autosomal gene must be abnormal for a genetic condition or disease to occur. An autosomal gene is a gene that is located on one of the autosomes or non-sex chromosomes. When both parents have one abnormal copy of the same gene, they have a 25% chance with each pregnancy that their offspring will have the disorder.

AUTOSOME. A chromosome not involved in sex determination.

AVASCULAR NECROSIS. A disorder in which bone tissue dies and collapses following the temporary or permanent loss of its blood supply; it is also known as osteonecrosis.

AVIAN CHLAMYDIOSIS. An illness in pet birds and poultry caused by *Chlamydia psittaci*. It is also known as parrot fever in birds.

AVULSE. To pull or tear away forcibly. In some cases, a surgeon must remove a nail by avulsing it from its matrix.

AVULSION. A ripping out or tearing away of a tooth or other body part.

AVULSION FRACTURE. A fracture caused by the tearing away of a fragment of bone where a strong ligament or tendon attachment forcibly pulls the fragment away from the bone tissue.

AXIAL. A straight line passing through a spherical body between its two poles and about which the body may revolve.

AXILLA. Armpit.

AXILLARY LYMPH NODE. Lymph nodes under the arm.

AXIS. A line that passes through the center of the body or body part.

AXON. The long extension of a nerve fiber that generally conducts impulses away from the body of the nerve cell.

AYURVEDA. A system of holistic medicine from India that aims to bring the individual into harmony with nature.

AYURVEDIC MEDICINE. A system of holistic medicine from India that aims to bring the individual into harmony with nature.

AZOTEMIA. The presence of excess nitrogenous wastes in the blood.

B

B CELL. A type of lymphocyte, or white blood cell, that is a key component of the body's immune system. Mature B cells produce immunoglobulins.

B CELL LYMPHOMAS. Non-Hodgkin's lymphomas that arise from B cells.

B LYMPHOCYTE. A type of lymphocyte, or white blood cell, that is a key component of the body's immune system. Mature B cells produce immunoglobulins.

B VITAMINS. This family of vitamins consists of thiamine (B_1), riboflavin (B_2), niacin (B_3), pantothenic acid (B_5), pyridoxine (B_6), biotin, folic acid (B_9), and cobalamin (B_{12}). They are interdependent and involved in converting glucose to energy.

BABINSKI REFLEX. A reflex movement by the big toe when the sole is tickled; an upward response is normal in infancy, but indicates central nervous system damage in older children and adults.

BACILLUS. A rod-shaped bacterium.

BACILLUS CALMETTE-GUÉRIN (BCG). A vaccine made from a weakened bacillus similar to the tubercle bacillus, which may help prevent serious pulmonary TB and its complications.

BACTEREMIA. The presence of bacteria in the bloodstream.

BACTERIA. Tiny, one-celled forms of life that cause many diseases and infections.

BACTERIAL OSTEOMYELITIS. An infection of the bone or bone marrow that is caused by a bacterium.

BACTERIAL VAGINITIS. This is the term for inflammation of the vagina due to a bacterial infection.

BACTERICIDAL. An agent that destroys bacteria (e.g., *Staphylococci aureus, Streptococci pneumoniae, Escherichia coli, Salmonella enteritidis*).

BACTERIUM. A single-celled microorganism that can be seen only through a microscope. Many bacteria cause disease.

BACTERIURIA. The presence of bacteria in the urine.

BALANITIS XEROTICA OBLITERANS (BXO). A chronic, progressive, hardening skin inflammation of the penis.

BALLOON ANGIOPLASTY. A procedure in which a balloon catheter is used to mechanically dilate the affected area of a diseased artery and enlarge the constricted or narrowed segment.

BAND CELL. An immature neutrophil at the stage just preceding a mature cell. The nucleus of a band cell is unsegmented.

BARBITURATES. A group of medicines that slow breathing and lower the body temperature and blood pressure. They can be habit forming and are now used chiefly for anesthesia.

BARIATRIC. The branch of medicine that deals with the prevention and treatment of obesity and related disorders.

BARIATRIC SURGERY. Procedures such as gastric bypass or banding surgeries for treating obesity and type 2 diabetes.

BARIUM. A chemical used in certain radiological studies to enhance visualization of anatomical structures.

BARIUM ENEMA. An x-ray test of the bowel performed after giving the patient an enema of a white chalky substance (barium) that outlines the colon and the rectum.

BARIUM SULFATE. A barium compound used during a barium enema to block the passage of x-rays during the exam.

BARIUM SWALLOW. Barium is used to coat the throat to highlight the tissues lining the throat, allowing them to be visualized using x-ray pictures.

BARIUM X RAY (UPPER GI). An x-ray test of the upper part of the gastrointestinal (GI) tract (including the esophagus, stomach, and a small portion of the small intestine) after the patient is given a white, chalky barium sulfate solution to drink. This substance coats the upper GI and the x rays reveal any abnormality in the lining of the stomach and the upper GI.

BAROTRAUMA. Ear pain caused by unequal air pressure on the inside and outside of the ear drum. Barotrauma, which is also called pressure-related ear pain or barotitis media, is the most common reason for myringotomies in adults.

BARRETT'S ESOPHAGUS. A condition in which the esophageal tissue closest to the stomach contains highly abnormal cells that have a great likelihood of converting to frank cancer.

BARRETT'S SYNDROME. Also called Barrett's esophagus or Barrett's epithelia, this is a condition where the squamous epithelial cells that normally line the esophagus are replaced by thicker columnar epithelial cells.

BARTHOLIN'S GLANDS. These glands are embedded in the vestibule of the vagina and function to maintain moisture.

BASAL CELL. A keratinocyte in the basal layer, the deepest of the five layers of cells in the epidermis.

BASAL CELL CANCER. The most common form of skin cancer; it usually appears as one or several nodules having a central depression. It rarely spreads (metastasizes), but is locally invasive.

BASAL GANGLIA. A group of masses of gray matter located in the cerebral hemispheres of the brain that control movement as well as some aspects of emotion and cognition.

BASELINE. A return to an original state.

BASOPHIL. Segmented white blood cell with large dark blue-black granules that releases histamine in allergic reactions.

B-COMPLEX VITAMINS. A group of water-soluble vitamins that often work together in the body. These include thiamin (B_1), riboflavin (B_2), niacin (B_3), pantothenic acid (B_5), pyridoxine (B_6), biotin (B_7 or vitamin H), folate/folic acid (B_9), and cobalamin (B_{12}).

BECKER MUSCULAR DYSTROPHY (BMD). A type of muscular dystrophy that affects older boys and men,

WWW.BOOKBAZ.IR

and usually follows a milder course than Duchenne muscular dystrophy.

BEHAVIOR MODIFICATION. A form of therapy that uses rewards to reinforce desired behavior. An example would be to give a child a piece of chocolate for grooming himself or herself appropriately.

BEHAVIORAL. Means related to the way a person acts.

BEHAVIORAL THERAPY. An approach to treatment that focuses on extinguishing undesirable behavior and replacing it with desired behavior.

BEM SEX ROLE INVENTORY (BSRI). A 60-item self-administered test that researchers often use to measure psychological androgyny in test subjects. It was devised in 1971 by Sandra Bem.

BENCE JONES PROTEIN. Light chain of an immunoglobulin that is overproduced in multiple myeloma and is excreted in the urine.

BENIGN. Not malignant, noncancerous.

BENIGN PROSTATE HYPERPLASIA (BPH). A noncancerous condition of the prostate that causes overgrowth of the prostate tissue, thus enlarging the prostate and obstructing urination.

BENIGN PROSTATIC HYPERTROPHY (BPH). An enlargement of the prostate that is not cancerous. However, it may cause problems with urinating or other symptoms.

BENIGN TUMOR. A localized overgrowth of cells that does not spread to other parts of the body.

BENZENE. A colorless volatile flammable toxic liquid hydrocarbon used as a solvent and as a motor fuel.

BENZODIAZEPINES. A class of drugs that have a hypnotic and sedative action, used mainly as tranquilizers to control symptoms of anxiety.

BERYLLIUM. A steel-grey, metallic mineral used in the aerospace and nuclear industries and in a variety of manufacturing processes.

BETA 2-MICROGLOBULIN. Protein produced by B-cells; high concentrations in the blood are indicative of multiple myeloma.

BETA RADIATION. Streams of electrons emitted by beta emitters like carbon-14 and radium.

BETA-2 MICROGLOBULIN; B2M. A protein found on the surface of many cells, particularly white blood cells.

BETA-AGONIST. Beta-adrenergic agonist; a drug the binds to beta receptors to cause adrenergic effects such as bronchodilation.

BETA-AMYLOID PLAQUES. Senile plaques; structures in the brain, composed of dead or dying nerve cells and cell debris surrounding deposits of beta-amyloid protein, that are diagnostic of AD. Beta-amyloid forms when amyloid precursor protein (APP) is not broken down properly.

BETA-BLOCKER. An antihypertensive (blood pressure-lowering) drug that limits the activity of epinephrine, a hormone that increases blood pressure.

BETA-CAROTENE. A carotenoid provitamin A in dark green and yellow fruits and vegetables that has one-twelfth the vitamin A activity of retinol.

BETA-HCG (BETA-HUMAN CHORIONIC GONADOTROPIN). A tumor marker associated with testicular cancer and tumors, such as choriocarcinoma and molar pregnancies, that begin in placental cells called trophoblasts.

BETA-LACTAMASE. Bacterial enzymes that inactive antibiotics with beta-lactam rings, such as penicillins and cephalosporins.

BIBLIOTHERAPY. The use of books (usually self-help or problem-solving works) to improve one's understanding of personal problems and/or to heal painful feelings.

BICEPS. The muscle in the front of the upper arm.

BICUSPID. Premolar; the two-cupped tooth between the first molar and the cuspid.

BIFIDOBACTERIA. A group of bacteria normally present in the intestine. Commercial supplements containing these bacteria are available.

BILATERAL. Located on or affecting both sides of the body.

BILE. A liquid secreted by the liver and passed through ducts to the small intestine where it aids in the digestion and absorption of fats.

BILE ACID. A detergent that is made in the liver and excreted into the intestine to aid in the absorption of fats.

BILE DUCTS. Tubes that carry bile, a thick yellowish-green fluid that is made by the liver, stored in the gallbladder, and helps the body digest fats.

BILIARY. Of bile or of the gallbladder and bile ducts that transport bile and make up the biliary system or tract.

BILIARY ATRESIA. The underdevelopment or absence of bile ducts.

BILIARY SYSTEM. The gallbladder and the system of tubes that carries bile from the liver into the intestine.

BILIARY TRACT. The passages that allow the flow of bile from the gallbladder to the intestines.

BILIRUBIN. A red-yellow pigment in the bile and blood; excessive accumulation of bilirubin results in jaundice.

BILIVERDIN. A green bile pigment formed from the oxidation of heme, which is a bilin with a structure almost identical to that of bilirubin.

BINGE DRINKING. Consumption of five or more alcoholic drinks in a row on a single occasion.

BINGE EATING DISORDER. A condition characterized by uncontrolled eating.

BINOCULAR. Both eyes accurately pointing to the same object.

BINOCULAR FIXATION. Both eyes pointed to and looking at the same object.

BINOCULAR VISION. Using both eyes at the same time to see an image.

BIOAVAILABILITY. Availability to living organisms, based on chemical form.

BIOCHEMICAL TESTING. Measuring the amount or activity of a particular enzyme or protein in a sample of blood or urine or other tissue from the body.

BIODIVERSITY. The range of organisms present in a defined ecological system.

BIOENERGETICS. A system of therapy that combines breathing and body exercises, psychological therapy, and the free expression of emotions to release blocked physical and psychic energy.

BIOFEEDBACK. A technique in which a person is taught to consciously control the body's response to a stimulus.

BIOFIELD HEALING. A general term for a group of alternative therapies based on the belief that the human body is surrounded by an energy field (or aura) that reflects the condition of the person's body and spirit. Rebalancing or repairing the energy field is thought to bring about healing in mind and body. Reiki, therapeutic touch, polarity balancing, Shen therapy, and certain forms of color therapy are considered forms of biofield healing.

BIOINFORMATICS. The use of computer science for collecting, classifying, and analyzing biochemical and genetic information.

BIOLOGIC RESPONSE MODIFIER (BRM). Immunotherapy; a class of drugs used to treat rheumatoid arthritis by inhibiting components of the immune system.

BIOLOGIC THERAPY. Targeted therapy; use of monoclonal antibodies to inactivate or destroy HER2-positive breast cancer cells.

BIOLOGICAL CLOCK. A synonym for the body's circadian rhythm, the natural biological variations that occur over the course of a day.

BIOLOGICAL PSYCHIATRY. An approach to psychiatry that aims to understand mental disorders in terms of the biological and biochemical functions of the central nervous system.

BIOLOGICAL TISSUE VALVE. A replacement heart valve that is harvested from the patient (autograft), a human cadaver (homograft or allograft), or other animal, such as a pig (heterograft).

BIOLOGICS. Naturally occurring compounds in the human body, usually proteins, that are used to treat disease.

BIOMARKER. A biochemical substance that can be detected in blood samples and indicates the presence of a cancerous tumor.

BIOMECHANICS. The application of mechanical laws to the structures in the human body, such as measuring the force and direction of stresses on a joint.

BIOPSY. Surgical removal of tissue for microscopic examination.

BIOSYNTHESIS. The manufacture of materials in a biological system.

BIOTERRORISM. The intentional use of disease-causing microbes or other biologic agents to intimidate or terrorize a civilian population for political or military reasons.

BIOTIN. A B-vitamin, vitamin B_7, also called vitamin H or coenzyme R.

BIOTYPE. A variant strain of a bacterial species with distinctive physiological characteristics.

BIPOLAR DISORDER. A mood disorder marked by alternating episodes of extremely low mood (depression) and exuberant highs (mania).

WWW.BOOKBAZ.IR

BIRTH ASPHYXIA. Dangerous oxygen deprivation in newborns.

BISMUTH. A substance used in medicines to treat diarrhea, nausea, and indigestion.

BISPHOSPHONATES. Compounds that slow bone loss and increase bone density.

BLACKHEAD. A plug of fatty cells capped with a blackened mass.

BLADDER. The bladder is located in the lower part of the abdomen; it is a structure like a small balloon that collects urine for temporary storage and is emptied from time to time by urinating.

BLADDER IRRIGATION. To flush or rinse the bladder with a stream of liquid (as in removing a foreign body or medicating).

BLADDER MUCOSA. Mucous coat of the bladder.

BLADDER TRAINING. A behavioral modification program used to treat stress incontinence. Bladder training involves putting the patient on a toilet schedule, and gradually increasing the time interval between urination.

BLADDER TUMOR MARKER STUDIES. A test to detect specific substances released by bladder cancer cells into the urine using chemicals or immunology (using antibodies).

BLADDER WASHING. A procedure in which bladder washing samples are taken by placing a salt solution into the bladder through a catheter (tube) and then removing the solution for microscopic testing.

BLAST PHASE. Stage of chronic myelogenous leukemia where large quantities of immature cells are produced by the marrow, and it is not responsive to treatment.

BLASTEMAL. An immature material from which cells and tissues develop.

BLASTOCYST. A cluster of cells representing multiple cell divisions that have occurred in the Fallopian tube after successful fertilization of an ovum by a sperm. This is the developmental form which must leave the Fallopian tube, enter the uterus, and implant itself in the uterus to achieve actual pregnancy.

BLEACHING. Technique used to brighten stained teeth.

BLEEDING DISORDER. A problem related to the clotting mechanism of the blood.

BLENDED FAMILY. A family formed by the remarriage of a divorced or widowed parent. It includes the new husband and wife, plus some or all of their children from previous marriages.

BLEPHAROPLASTY. Surgical reshaping of the eyelid.

BLOGGING. Creating and maintaining an online personal website, in most cases allowing readers to add comments. The term comes from the word weblog, or online diary.

BLOOD ALCOHOL CONCENTRATION OR CONTENT (BAC). A measure of the amount of alcohol in the body; in most states, legal alcohol intoxication is defined as a BAC of at least 0.08 grams per deciliter of blood.

BLOOD BANK. A laboratory that specializes in blood typing, antibody identification, and transfusion services.

BLOOD CELL. Cellular component of blood. There are three general types: white blood cells, red blood cells, and platelets, all which are produced in the bone marrow.

BLOOD CLOT. A thickening of the blood into a jelly-like substance that helps stop bleeding. Clotting of the blood within a blood vessel can lead to blockage of blood flow.

BLOOD CULTURE. A procedure where blood is collected from a vein and is placed in a small bottle that contains a special liquid; the liquid will make any organisms that are present in the blood sample grow. These organisms can then be grown and identified in the laboratory so that the proper antibiotic can be given to the patient.

BLOOD GLUCOSE. The main sugar that the body makes from the food in the diet.

BLOOD PERFUSION. A physiological term that refers to the process of nutritive delivery of arterial blood to a capillary bed in the biological tissue.

BLOOD TYPE. Blood categories based on the presence or absence of certain antigens on the red blood cells.

BLOOD UREA NITROGEN (BUN). A waste product that is formed in the liver and collects in the bloodstream; patients with kidney failure have high BUN levels.

BLOOD VESSELS. General term for arteries, veins, and capillaries that transport blood throughout the body.

BLOOD-BRAIN BARRIER. A specialized, semi-permeable layer of cells around the blood vessels in the brain that controls which substances can leave the circulatory system and enter the brain.

BODY IMAGE. A person's sense of his or her physical appearance, often shaped by social standards of attractiveness as well personal experiences.

BODY MASS INDEX (BMI). A measurement that has replaced weight as the preferred determinant of obesity. The BMI can be calculated (in English units) as 703.1 times a person's weight in pounds divided by the square of the person's height in inches.

BODY PLETHYSMOGRAPHY. A very sensitive test given to measure damage to the lungs that might be missed by routine pulmonary function tests. The patient sits within an airtight box while various devices measure both the air pressure in the patient's alveoli and the airflow through the respiratory system.

BODYWORK. A term that covers a variety of therapies that include massage, realignment of the body, and similar techniques to treat deeply ingrained stresses and traumas carried in the tissues of the body.

BOLUS. A mass of food ready to be swallowed, or a preparation of medicine to be given by mouth or IV all at once rather than gradually.

BONDING. Rebuilding, reshaping, and covering tooth defects using tooth-colored materials.

BONE DENSITOMETRY. A test that quickly and accurately measures the density of bone.

BONE MARROW. A spongy tissue located within flat bones, including the hip and breast bones and the skull. This tissue contains stem cells, the precursors of platelets, red blood cells, and white blood cells.

BONE MARROW ASPIRATION AND BIOPSY. A procedure in which a needle is inserted into the large bones of the hip or spine and a small piece of marrow is removed for microscopic examination.

BONE MARROW BIOPSY. A procedure in which a needle is inserted into the large bones of the hip or spine and a small piece of marrow is removed for microscopic examination.

BONE MARROW SUPPRESSION. A decrease in cells responsible for providing immunity, carrying oxygen, and those responsible for normal blood clotting.

BONE MARROW TRANSPLANT. A procedure in which a quantity of bone marrow is extracted through a needle from a donor, and then passed into a patient to replace the patient's diseased or absent bone marrow.

BONE MORPHOGENETIC PROTEINS. A family of substances in human bones and blood that encourage the process of osteoinduction.

BONE SCAN. An x-ray study in which patients are given an intravenous injection of a small amount of a radioactive material that travels in the blood. When it reaches the bones, it can be detected by an x ray to make a picture of their internal structure.

BONE SPUR. Also called an osteophyte, it is an outgrowth or ridge that forms on a bone.

BOOSTER. A supplementary dose of an immunizing agent.

BORDERLINE PERSONALITY DISORDER (BPD). A pattern of behavior characterized by impulsive acts, intense but chaotic relationships with others, identity problems, and emotional instability.

BORDETELLA PERTUSSIS; B. PERTUSSIS. The bacterium that causes whooping cough.

BORRELIA BURGDORFERI; B. BURGDORFERI. The tick-borne spirochete bacterium that causes Lyme disease.

BORRELIOSIS. Disease caused by bacteria of the genus *Borrelia*.

BOTULINUM TOXIN (BOTULIN). Any of a group of potent bacterial toxins or poisons produced by different strains of the bacterium *Clostridium botulinum*. The toxins cause muscle paralysis.

BOTULISM. Life-threatening paralytic food poisoning caused by botulinum toxin from the bacterium *Clostridium botulinum*.

BOUGIE. A mercury-filled dilator in the shape of a cylinder or tapered cylinder. Bougies come in a range of different sizes.

BOUGIENAGE. The procedure of dilating tubal organs, like the esophagus, with a bougie or bougies.

BOVINE SPONGIFORM ENCEPHALOPATHY. Also known as Mad Cow disease, a progressive, fatal disease of the nervous system of domestic animals that is transmitted by eating infected food.

BOWEL. The part of the intestines that is connected to the anus.

BOWEL LUMEN. The space within the intestine.

WWW.BOOKBAZ.IR

BOWEL OBSTRUCTION. A blockage in the intestine which prevents the normal flow of waste down the length of the intestine.

BOWMAN'S CAPSULE. The structure surrounding the glomerulus.

BRACES. An orthodontic appliance consisting or brackets cemented to the surface of each tooth and wires of stainless steel or nickel titanium alloy. Braces are used to treat malocclusion by changing the position of the teeth.

BRACHYTHERAPY. A form of radiation therapy in which small pellets of radioactive material are placed inside or near the area to be treated. It is also known as internal radiation therapy or sealed-source radiotherapy.

BRADYCARDIA. A resting heart rate of under 60 beats per minute.

BRADYKINESIA. Extremely slow movement.

BRAIN DEATH. The posterior portion of the brain that connects directly to the spinal cord. It regulates breathing, heart function, and the sleep-wake cycle as well as maintaining consciousness.

BRAIN STEM. The posterior portion of the brain that connects directly to the spinal cord. It regulates breathing, heart function, and the sleep-wake cycle as well as maintaining consciousness.

BRAXTON HICKS CONTRACTIONS. Tightening of the uterus or abdomen that can occur throughout pregnancy. These contractions do not cause changes to the cervix and are sometimes called false labor or practice contractions.

BRCA1 AND BRCA2. BReast CAncer susceptibility genes; certain mutations in these genes greatly increase the risk for breast cancer, as well as ovarian cancer.

BREAST AUGMENTATION. A surgery to increase the size of the breasts.

BREAST BIOPSY. A procedure in which suspicious tissue is removed and examined by a pathologist for cancer or other disease. The breast tissue may be obtained by open surgery or through a needle.

BREAST SELF-EXAM (BSE). A five-step monthly procedure for women to detect lumps or other changes in their breasts.

BREAST-CONSERVING SURGERY. Breast cancer treatment, such as a lumpectomy or partial mastectomy, that removes only the cancerous tissue rather than the entire breast.

BREATHING RATE. The number of breaths per minute.

BREECH POSITION. Birth of a baby bottom-first, instead of the usual head first delivery. This can add to labor and delivery problems because the baby's bottom does not mold a passage through the birth canal as well as the head does.

BRIDGE. An appliance of one or more artificial teeth anchored by crowns on the adjacent teeth.

BRIEF PSYCHOTIC DISORDER. An acute, short-term episode of psychosis lasting no longer than one month. This disorder may occur in response to a stressful event.

BRIQUET'S SYNDROME. Another name for somatization disorder.

BROCA'S APHASIA. A condition characterized by either partial or total loss of the ability to express oneself, either through speech or writing. Hearing comprehension is not affected. This condition may result from a stroke, head injury, brain tumor, or infection.

BROMOCRIPTINE. Also known as Parlodel, the main drug used to treat galactorrhea by reducing levels of the hormone prolactin.

BRONCHI. The network of tubular passages that carry air to the lung and allow air to be expelled from the lungs.

BRONCHIAL. Relating to the air passages to and from the lungs including the bronchi and the bronchioles.

BRONCHIAL LAVAGE. A procedure that involves repeatedly washing the inside of the bronchial tubes of the lung.

BRONCHIAL TUBES. The major airways to the lungs and their main branches.

BRONCHIECTASIS. Persistent and progressive dilation of bronchi or bronchioles as a consequence of inflammatory disease such as lung infections, obstructions, tumors, or congenital abnormality.

BRONCHIOLE. A thin air passage in the lung that branches off a larger airway.

BRONCHIOLES. Small airways extending from the bronchi into the lobes of the lungs.

BRONCHITIS. Inflammation of the mucous membrane of the bronchial tubes of the lung that can make it difficult to breathe.

BRONCHOALVEOLAR LAVAGE. Washing cells from the air sacs at the end of the bronchioles.

BRONCHODILATOR. A drug that relaxes bronchial muscles resulting in expansion of the bronchial air passages.

BRONCHOPLEURAL FISTULA. An abnormal connection between an air passage and the membrane that covers the lungs.

BRONCHOSCOPE. A lighted, flexible tube inserted into the windpipe to view the bronchi or withdraw fluid samples for testing.

BRONCHOSCOPY. A procedure in which a hollow, flexible tube is inserted into the airway to allow visual examination of the larynx, trachea, bronchi, and bronchioles. It is also used to collect specimens for biopsy or culturing and to remove airway obstructions.

BRONCHOSCOPY SCAN. A procedure in which a hollow, flexible tube is inserted into the airway to allow visual examination of the larynx, trachea, bronchi, and bronchioles. It is also used to collect specimens for biopsy or culturing and to remove airway obstructions.

BRONCHUS. One of the two large tubes connecting the windpipe and the lungs.

BRUCH'S MEMBRANE. A membrane in the eye between the choroid membrane and the retina.

BRUIT. A roaring sound created by a partially blocked artery.

BRUTON'S AGAMMAGLOBULINEMIA TYROSINE KINASE (BTK). An enzyme vital for the maturation of B cells.

BRUXISM. Habitual clenching and grinding of the teeth, especially during sleep.

BUBO. A tender, swollen lymph node in the groin that may follow a chancroid ulcer.

BUBOES. Smooth, oval, reddened, and very painful swellings in the armpits, groin, or neck that occur as a result of infection with the plague.

BUCCAL. Pertaining to the mouth or cheeks. It is derived from the Latin word for cheek.

BUCK'S FASCIA. The deep connective tissue of the penis.

BUERGER'S DISEASE. An episodic disease that causes inflammation and blockage of the veins and arteries of the limbs. It tends to be present almost exclusively in men under age 40 who smoke, and may require amputation of the hand or foot.

BUFFY COAT. The thin layer of concentrated white blood cells that forms when a tube of blood is spun in a centrifuge.

BULBAR MUSCLES. Muscles that control chewing, swallowing, and speaking.

BULIMIA NERVOSA. An eating disorder in which a person binges on food and then induces vomiting, uses laxatives, or goes without food for some time.

BUPROPION. An antidepressant medication given to smokers for nicotine withdrawal symptoms. It is sold under the trade name Zyban.

BURNOUT. An emotional condition marked by tiredness, loss of interest, or frustration that interferes with job performance. Burnout is usually regarded as the result of prolonged stress.

BURSAE. A closed sac lined with a synovial membrane and filled with fluid, usually found in areas subject to friction, such as where a tendon passes over a bone.

BURSITIS. Inflammation of a bursa, a fluid-filled cavity or sac. In the body, bursae are located at places where friction might otherwise develop.

BUSPIRONE. An antianxiety medication that is also given for withdrawal symptoms. It is sold under the trade name BuSpar.

BUTTERFLY BANDAGE. A narrow strip of adhesive with wider flaring ends (shaped like butterfly wings) used to hold the edges of a wound together while it heals.

BUTTON BATTERIES. Tiny, round batteries containing mercuric chloride that power items such as watches, hearing aids, calculators, cameras, and penlights.

BYPASS SURGERY. A surgical procedure that grafts blood vessels onto arteries to reroute the blood flow around blockages in the arteries (arteriosclerosis).

C

CA 15-3 (CANCER ANTIGEN 15-3). A tumor marker associated with breast cancer.

CA 19-9 (CANCER ANTIGEN 19-9). A tumor marker associated with pancreatic cancer.

WWW.BOOKBAZ.IR

CA 27-29 (BREAST CARCINOMA-ASSOCIATED ANTIGEN). A tumor marker associated with breast cancer.

CA 125 (CANCER ANTIGEN 125). A tumor marker associated with ovarian cancer.

CACHEXIA. Physical wasting and malnutrition, usually from chronic disease.

CADAVER. The medical and legal term for a human corpse used for dissection.

CADAVER ORGAN. A pancreas, kidney, or other organ from a brain-dead organ donor.

CADAVERIC DONOR. An organ donor who has recently died of causes not affecting the organ intended for transplant.

CADUCEUS. The ancient and universal symbol of medicine consisting of the winged staff of Mercury and two intertwining serpents.

CAGE. A four-question assessment for the presence of alcoholism in both adults and children.

CALCANEOUS. The heel bone.

CALCIFICATION. Hardening or stiffening due to calcium accumulation.

CALCIFIED. Hardened by calcium deposits.

CALCITONIN. A naturally occurring hormone made by the thyroid gland that can be used as a drug to treat osteoporosis and Paget's disease of the bone.

CALCIUM. A mineral that helps build bone. After menopause, women start making less of the bone-protecting hormone estrogen and may need to increase their intake of calcium.

CALCIUM CHANNEL BLOCKER. A drug that lowers blood pressure by regulating calcium-related electrical activity in the heart.

CALCULUS. A hardened yellow or brown mineral deposit from unremoved plaque; also called tartar.

CALDWELL-LUC PROCEDURE. A surgical procedure in which the surgeon enters the maxillary sinus by making an opening under the upper lip above the teeth.

CALICIVIRUS. A member of the Caliciviridae family of viruses that includes noroviruses.

CALLBACK. A follow-up examination for a patient whose initial mammogram (or other imaging test) yielded unclear results.

CALLUS. Thickened skin due to chronic rubbing or irritation.

CALORIC TESTING. Flushing warm and cold water into the ear stimulates the labyrinth and causes vertigo and nystagmus if all the nerve pathways are intact.

CALORIE. A unit of food energy.

CALORIE RESTRICTION. A (usually substantial) limit on the number of calories a person consumes.

CAMPYLOBACTER. A genus of bacteria that can cause food poisoning and are found in almost all raw poultry.

CANALICULI. Also known as lacrimal ducts, these tube-like structures carry the tears from the eyes to the lacrimal sac.

CANCER. The uncontrolled growth of abnormal cells that have mutated from normal tissues.

CANCER ANTIGEN. Marker proteins for some types of cancer.

CANCER STAGING. A surgical procedure to remove a lymph node and examine the cells for cancer. It determines the extent of the cancer and how far it has spread.

CANCER VACCINES. A treatment that uses the patient's immune system to attack cancer cells.

CANDIDIASIS. A common fungal infection caused by yeast that thrives in moist, warm areas of the body.

CANINE TOOTH. The two sharp teeth located next to the front incisor teeth in mammals that are used to grip and tear.

CANKER SORE. A painful sore inside the mouth.

CANNABINOID. Any one of a class of compounds that stimulate the cannabinoid receptor sites in the human body. In humans, cannabinoid receptors primarily affect the nervous system—including the brain, spinal cord, and peripheral nerves—and the immune system—which helps the body fight disease and infection. Cannabinoids are separated into three classifications: endocannabinoids (which are produced naturally within the body); phytocannabinoids (which are found in plants) including tetrahydrocannabinol (THC), the psychoactive component of cannabis; and synthetic cannabinoids (which are manufactured in a laboratory).

CANNULA. A tube inserted into a cavity to serve as a channel for the transport of fluid.

CAPILLARIES. The smallest of the blood vessels that bring oxygenated blood to tissues.

CAPILLARY BED. A dense network of tiny blood vessels that enables blood to fill a tissue or organ.

CAPSAICIN. An active ingredient from hot chili peppers that is used in topical ointments to relieve pain. It appears to work by reducing the levels of a chemical substance involved in transmitting pain signals from nerve endings to the brain.

CAPSAICIN. An active ingredient from hot chili peppers that is used in topical ointments to relieve pain. It appears to work by reducing the levels of a chemical substance involved in transmitting pain signals from nerve endings to the brain.

CAPSID. The outer protein coat of a virus.

CAPSULAR CONTRACTURE. Thick scar tissue around a breast implant, which may tighten and cause discomfort and/or firmness.

CARBAPENEMASE. An enzyme produced by CRE that makes the bacteria resistant to carbapenems by breaking the structure of the antibiotic.

CARBAPENEM-RESISTANT ENTEROBACTERIACEAE (CRE). A group of bacteria in the Enterobacteriaceae family that are increasingly resistant to carbapenem antibiotics. *Klebsiella* bacteria are one type of CRE.

CARBAPENEMS. A class of beta-lactam antibiotics with a broad spectrum of antibacterial activity. They are often considered antibiotics of last resort.

CARBOHYDRATE. Sugars, starches, celluloses, and gums that are a major source of calories and fiber from foods.

CARBON DIOXIDE. Abbreviated CO_2; a gas that produces light that is well absorbed by the skin, so is commonly used for skin resurfacing treatments.

CARBON MONOXIDE. A colorless, odorless, highly poisonous gas.

CARBON MONOXIDE DIFFUSING TEST. Also called the transfer factor test, this test measures the ability of the patient's lungs to transfer blood gases.

CARBONIC ANHYDRASE INHIBITOR. A class of diuretic drugs that inhibit the enzyme carbonic anhydrase, an enzyme involved in producing bicarbonate, which is required for aqueous humor production by the ciliary tissues in the eye. Thus, inhibitors of this enzyme inhibit aqueous humor production. Some side effects are urinary frequency, kidney stones, loss of the sense of taste, depression, and anemia.

CARBOXYHEMOGLOBIN (COHB). Hemoglobin that is bound to carbon monoxide instead of oxygen.

CARBUNCLE. A large, deep skin abscess formed by a group or cluster of boils.

CARCINOEMBRYONIC ANTIGEN (CEA). A fetal protein that is present at high levels in the blood with some types of cancer, such as breast or digestive-system cancers.

CARCINOGEN. Any substance or form of radiation that increases the risk of cancer or stimulates the growth of an existing cancer.

CARCINOID SYNDROME. The pattern of symptoms (often including asthma and diarrhea) associated with carcinoid tumors of the digestive tract or lungs.

CARCINOMA IN SITU. Cancer that is confined to the cells in which it originated and has not spread to other tissues.

CARDIAC ANGIOGRAPHY. A procedure used to visualize blood vessels of the heart. A catheter is used to inject a dye into the vessels; the vessels can then be seen by x ray.

CARDIAC ARREST. A condition in which the heart has no discernable electrical activity to stimulate contraction, therefore no blood is pumped.

CARDIAC ARRHYTHMIA. An abnormality in the rate or rhythm of the heartbeat.

CARDIAC CATHETERIZATION. A diagnostic procedure in which a thin tube is inserted into an artery or vein and guided to the heart using x-rays. The function of the heart and blood vessels can be evaluated using this technique.

CARDIAC DYSRHYTHMIAS. Abnormal heart rate, rhythm, or sequence of rhythms.

CARDIAC HYPERTROPHY. Thickening of the heart muscle.

CARDIAC MARKER. A substance in the blood that rises following a heart attack.

CARDIAC REHABILITATION. A structured program of education and activity offered by hospitals and other organizations.

CARDIAC SHUNT. A defect in the wall of the heart that allows blood from different chambers to mix.

CARDIAC SURGERY. Surgery performed on the heart.

CARDIAC TAMPONADE. Compression and restriction of the heart that occurs when the pericardium fills with blood or fluid. This increase in pressure outside the heart interferes with heart function and can result in shock and/or death.

CARDIOGENIC. Originating with the heart.

WWW.BOOKBAZ.IR

CARDIOLOGIST. Doctor who specializes in diagnosing and treating heart diseases.

CARDIOMEGALY. Referring to a medical condition in which the heart is larger than normal.

CARDIOMYOPATHY. A disease or disorder that affects the heart muscle.

CARDIOPULMONARY. Involving both heart and lungs.

CARDIOPULMONARY BYPASS. Mechanically circulating the blood with a heart-lung machine that bypasses the heart and lungs.

CARDIOPULMONARY BYPASS MACHINE. A mechanical instrument that takes over the circulation of the body while heart surgery is taking place.

CARDIOPULMONARY RESUSCITATION (CPR). A procedure for restoring normal breathing following cardiac arrest. It includes clearing the air passages, mouth-to-mouth artificial respiration, and heart massage by exerting pressure on the chest.

CARDIOVASCULAR. Pertaining to the heart and blood vessels.

CARDIOVASCULAR DISEASE. A structural or functional abnormality of the heart, or of the blood vessels supplying the heart, that impairs its normal function.

CARDIOVERSION. An electrical shock delivered to the heart to restore a normal rhythm.

CARDIOVERTER. A device to apply electric shock to the chest to convert an abnormal heartbeat into a normal heartbeat.

CARIES. The medical term for tooth decay.

CARNASSIALS. The last upper premolar teeth in the mouths carnivores, adapted to shear or puncture food. Carnassial teeth often cause puncture wounds when a cat bites a human.

CARNITINE PALMITOYLTRANSFERASE (CPT). An enzyme required for the utilization of certain fats for energy; an inherited CPT deficiency can cause exercise intolerance-induced rhabdomyolysis.

CARNIVORE. An animal whose diet consists mostly or entirely of meat. Cats, wolves, snakes, birds of prey, frogs, sharks, spiders, seals, and penguins are all carnivores.

CAROTENOIDS. Various common red and yellow pigments, such as beta-carotene, some of which have vitamin A and antioxidant activity.

CAROTID ARTERIES. The four principal arteries of the neck and head. There are two common carotid arteries, each of which divides into the two main branches (internal and external).

CAROTID ARTERY. One of the major arteries supplying blood to the head and neck.

CAROTID ARTERY DISEASE. A condition in which the arteries in the neck that supply blood to the brain become clogged, causing the danger of a stroke.

CAROTID ENDARTERECTOMY. A surgical technique for removing intra-arterial obstructions of the internal carotid artery.

CARPAL TUNNEL. A passageway in the wrist, created by the bones and ligaments of the wrist, through which the median nerve passes.

CARPAL TUNNEL SYNDROME. A condition caused by compression of the median nerve in the carpal tunnel of the hand, characterized by pain.

CARRIER. A person who possesses a gene for an abnormal trait without showing signs of the disorder. The person may pass the abnormal gene on to offspring.

CARRIER OIL. An oil used to dilute essential oils for use in massage and other skin care applications.

CARRIER STATE. The continued presence of an organism (bacteria, virus, or parasite) in the body that does not cause symptoms but is able to be transmitted and infect other persons.

CARTILAGE. A tough, elastic connective tissue found in the joints, outer ear, nose, larynx, and other parts of the body.

CASE MANAGER. A health-care professional who can provide assistance with a patient's needs beyond the hospital.

CASEIN HYDROLYSATE. A preparation made from the milk protein casein, which is hydrolyzed to break it down into its constituent amino acids. Amino acids are the building blocks of proteins.

CAST. An insoluble gelled protein matrix that takes the form of the renal tubule in which it was deposited. Casts are washed out by normal urine flow.

CATABOLIC. A metabolic process in which energy is released through the breakdown of complex molecules into simpler ones.

CATABOLISM. A metabolic process in which energy is released through the breakdown of complex molecules into simpler ones.

CATALYST. A substance that changes the rate of a chemical reaction, but is not physically changed by the process.

CATAPLEXY. A symptom of narcolepsy in which there is a sudden episode of muscle weakness triggered by emotions. The muscle weakness may cause the person's knees to buckle or the head to drop. In severe cases the patient may become paralyzed for a few seconds to minutes.

CATARACT. Progressive opacity or clouding of an eye lens, which obstructs the passage of light to the retina.

CATARRHAL STAGE. The first stage of whooping cough illness, during which the mucous membranes of the respiratory system become inflamed and produce excessive secretions.

CATATONIA. Psychomotor disturbance characterized by muscular rigidity, excitement, or stupor.

CATATONIC BEHAVIOR. Behavior characterized by muscular tightness or rigidity and lack of response to the environment. In some patients rigidity alternates with excited or hyperactive behavior.

CATECHOLAMINES. Hormones and neurotransmitters including dopamine, epinephrine, and norepinephrine.

CATHARSIS. Therapeutic discharge of emotional tension by recalling past events.

CATHARTIC. A medication or other agent that causes the bowels to empty.

CATHARTIC COLON. A poorly functioning colon, resulting from the chronic abuse of stimulant cathartics.

CATHETER. A hollow flexible tube that is inserted into a body cavity, duct, or vessel for the passage of fluids.

CATHETERIZATION. The process of inserting a hollow tube into a body cavity or blood vessel.

CATHODE. The negative electrode from which an electromagnetic current flows.

CATION. An ion carrying a positive charge due to a loss of electrons. Cations in the body include sodium, potassium, magnesium, and calcium ions.

CAT-SCRATCH DISEASE. An infectious disease caused by bacteria transmitted by the common cat flea that causes a self-limiting, mild infection in healthy people.

CAUDA EQUINA. A bundle of nerve roots in the lower (lumbar) region of the spinal canal that controls the leg muscles and functioning of the bladder, intestines, and genitals.

CAUDA EQUINA SYNDROME (CES). A group of symptoms characterized by numbness or pain in the legs and/or loss of bladder and bowel control, caused by compression and paralysis of the nerve roots in the cauda equina.

CAUSALGIA. A severe burning sensation sometimes accompanied by redness and inflammation of the skin. Causalgia is caused by injury to a nerve outside the spinal cord.

CAUTERIZE. To use heat or chemicals to stop bleeding, prevent the spread of infection, or destroy tissue.

CAUTERY. To use heat or chemicals to stop bleeding, prevent the spread of infection, or destroy tissue.

CAVITY. A hole or weak spot in the tooth surface caused by decay.

CCR5. A protein receptor on the surface of white blood cells that, along with CD4, is required by many HIV strains for entering host cells.

CD4. A type of protein molecule in human blood, sometimes called the T4 antigen, that is present on the surface of 65% of immune cells. The HIV virus infects cells with CD4 surface proteins (CD4+ cells), and as a result, depletes the number of immune system cells in the individual's blood. Most of the damage to an the immune system of an HIV-infected individual is done by viral destruction of CD4+ T cells.

CD4 COUNT. A measure of the strength of the immune system. HIV continually kills CD4 cells. Over time, the body can not replace these lost CD4 cells and their number declines. AS this happens, the body becomes more susceptible to infections. A normal CD4 count is 1000. The body starts to get more frequent common infections at around a count of 400. At around a CD4 count of 200, the body becomes susceptible to many unusual infections. It is best to start medications for HIV before the CD4 count drops below 200 to prevent these infections from developing.

CECUM. The beginning of the large intestine and the place where the appendix attaches to the intestinal tract.

CELIAC DISEASE. Inability to digest wheat protein (gluten), which causes weight loss, lack of energy, and pale, foul-smelling stools.

WWW.BOOKBAZ.IR

CELL. The smallest living units of the body which group together to form tissues and help the body perform specific functions.

CELL DIFFERENTIATION. The process by which stem cells develop into different types of specialized cells such as skin, heart, muscle, and blood cells.

CELLULITE. Dimpled skin that is caused by uneven fat deposits beneath the surface.

CELLULITIS. Inflammation of tissue due to infection.

CENTRAL LINE. A tube placed by needle into a large, central vein of the body.

CENTRAL NERVOUS SYSTEM (CNS). The brain and spinal cord.

CENTRAL NERVOUS SYSTEM (CNS) DEPRESSANT. Any drug that tends to reduce the activity of the central nervous system. The major drug categories included in this classification are: alcohol, anesthetics, antianxiety medications, antihistamines, antipsychotics, hypnotics, narcotics, sedatives, and tranquilizers.

CENTRAL OBESITY. A condition in which a person has excessive amounts of fat around the waist and inside the peritoneal cavity.

CENTRAL PRECOCIOUS PUBERTY (CPP). Precocious puberty resulting from the early maturation of the HPG axis.

CENTRAL RETINAL ARTERY. A branch of the ophthalmic artery that supplies blood to the retina and branches to form the arterioles of the retina.

CENTRAL RETINAL VEIN. Central blood vessel and its branches that drains the retina.

CENTROMERE. The centromere is the constricted region of a chromosome. It performs certain functions during cell division.

CEPHALOPELVIC DISPROPORTION (CPD). Occurs when the fetus's head is larger than the mother's pelvic inlet.

CERCARIA. The free-living form of the schistosome worm that has a tail, swims, and has suckers on its head for penetration into a host.

CEREBELLAR. Involving the cerebellum, which controls walking, balance, and coordination.

CEREBELLUM. The part of the brain involved in coordination of movement, walking, and balance.

CEREBRAL. Pertaining to the brain.

CEREBRAL ANEURYSM. The dilation, bulging, or ballooning out of part of the wall of a vein or artery in the brain.

CEREBRAL ANGIOGRAPHY. A medical test in which an x-ray visible dye is injected into blood vessels to allow them to be imaged on an x ray.

CEREBRAL CORTEX. Brain region responsible for reasoning, mood, and perception.

CEREBRAL EDEMA. Movement of water into brain cells causing the cells to swell, which disrupts normal functioning of the cells.

CEREBRAL EMBOLISM. Ischemic stroke caused by a blood clot that travels to the brain from elsewhere in the body.

CEREBRAL PALSY. Brain damage before, during, or just after birth that results in lack of muscle coordination and problems with speech.

CEREBRAL THROMBOSIS. Ischemic stroke caused by a blood clot that forms in an artery in the brain.

CEREBRAL VASCULAR ACCIDENT (CVA). A stroke.

CEREBROSIDES. Fatty carbohydrates that occur in the brain and nervous system.

CEREBROSPINAL FLUID (CSF). Fluid produced within the brain for nutrient transport and structural purposes. CSF circulates through the ventricles, open spaces within the brain, and drains through the membranes surrounding the brain.

CEREBROSPINAL FLUID ANALYSIS. An analysis of fluid that surrounds and protects the spinal cord and brain to indicate the presence of viruses, bacteria, and blood.

CEREBROVASCULAR ACCIDENT. Brain hemorrhage, also known as a stroke.

CEREBROVASCULAR DISEASE. Disorders affecting the blood vessels that supply the brain that may result in a stroke.

CERULOPLASMIN. A protein circulating in the bloodstream that binds with copper and transports it.

CERUMEN. The medical term for earwax.

CERVICAL. Relating to the top part of the spine that is composed of the seven vertebrae of the neck and the disks that separate them.

CERVICAL CANCER. Cancer of the entrance to the uterus. The cervix is the lower, narrow part of the uterus.

CERVICAL CANCER SCREENING. Use of the Papanicolaou (Pap) smear test to detect cervical cancer in the early curable stage.

CERVICAL CERCLAGE. A procedure in which the cervix is sewn closed; used in cases when the cervix starts to dilate too early in a pregnancy to allow the birth of a healthy baby.

CERVICAL DYSPLASIA. Dysplasia is the abnormal growth of the epithelial cells. This is what a Pap smear will detect in the cervix.

CERVICAL INTRAEPITHELIAL NEOPLASIA (CIN). A term used to categorize degrees of dysplasia arising in the epithelium, or outer layer, of the cervix.

CERVICAL POLYPS. Growths originating from the surface of the cervix or endocervical canal. These small, fragile growths hang from a stalk and protrude through the cervical opening (the os).

CERVICITIS. Cervicitis is an inflammation of the cervix or neck of the uterus.

CERVIX. The narrow outer end of the uterus that separates the uterus from the vaginal canal.

CESAREAN DELIVERY ON MATERNAL REQUEST (CDMR). The choice to have a cesarean delivery when it is not medically necessary.

CESAREAN SECTION. C-section; infant delivery through an incision in the abdominal and uterine walls.

CESTODIASIS. Parasitic infection caused by the presence of adult tapeworms of the class Cestoda within the intestinal tract. Infection is caused by accidental consumption of tapeworm larvae.

CGG OR CGG SEQUENCE. Shorthand for the DNA sequence: cytosine-guanine-guanine. Cytosine and guanine are two of the four molecules, otherwise called nucleic acids, that make up DNA.

CHAGAS DISEASE. A parasitic disease that causes mild early swelling at the site of the infection then becomes asymptomatic for many years but later may cause serious heart and digestive system problems. Parasites causing this disease are most common in rural Central and South America.

CHAKRA. One of seven major energy centers in the body, as defined by Hindu and yoga philosophy.

CHANCRE. An open sore with a firm or hard base that is the initial skin ulcer of primary syphilis.

CHARACTER. An individual's set of emotional, cognitive, and behavioral patterns learned and accumulated over time.

CHARACTER DISORDER. Another name for personality disorder.

CHELATE. A chemical that binds to heavy metals in the blood, thereby helping the body to excrete them in urine.

CHELATION. The process by which a molecule encircles and binds to a metal and removes it from tissue.

CHELATION THERAPY. Treatment with chemicals that bind to a poisonous metal and help the body pass it in urine at a faster rate.

CHELATORS. Various compounds that bind to metals such as mercury.

CHEMO BRAIN. A term used to describe problems with memory, concentration, or thinking clearly following chemotherapy.

CHEMO PREVENTATIVE. Description of a drug given in order to prevent the development of a specific disease.

CHEMORECEPTOR TRIGGER ZONE (CTZ). An area within the area postrema that is sensitive to bloodborne drugs and neurotransmitters; it communicates with other nearby brain structures to trigger vomiting.

CHEMOTHERAPY. A cancer treatment that uses synthetic drugs to destroy the tumor either by inhibiting the growth of the cancerous cells or by killing the cancer cells.

CHEST X RAY. Brief exposure of the chest to radiation to produce an image of the chest and its internal structures.

CHI. Basic life energy.

CHIARI II ANOMALY. A structural abnormality of the lower portion of the brain (cerebellum and brain stem) associated with spina bifida. The lower structures of the brain are crowded and may be forced into the foramen magnum, the opening through which the brain and spinal cord are connected.

CHIKUNGUNYA. An emerging viral disease similar to zika fever that is transmitted by mosquitoes and is spreading globally.

CHILD DEVELOPMENT. The process of physical, intellectual, emotional, and social growth that occurs from infancy through adolescence. Erik Erikson, Margaret Mahler, Sigmund Freud, and Jean Piaget are among the most well-known child development theorists.

WWW.BOOKBAZ.IR

CHILDREN'S HEALTH INSURANCE PROGRAM (CHIP). Children's Medicaid; a federal program administered by the states that provides low-cost or free health insurance to children from families with incomes that have traditionally been too high to qualify for Medicaid.

CHILDREN'S HOSPICE. A holistic philosophy that addresses the physical, emotional, social, and spiritual needs of children with life-threatening illnesses, as well as the needs of their families.

CHIROPRACTIC. A form of manipulative therapy that emphasizes the adjustment and realignment of joints and muscles. Chiropractic is most often used as an alternative treatment for low back pain.

CHLAMYDIA. The most common bacterial sexually transmitted disease in the United States that often accompanies gonorrhea and is known for its lack of evident symptoms in the majority of women.

CHLAMYDIA PSITTACI. An organism related to bacteria that infects some types of birds and can be transmitted to humans to cause parrot fever.

CHLAMYDIOSIS, PSITTACOSIS, OR ORNITHOSIS. Other names for parrot fever in humans.

CHLOASMA. A skin discoloration common during pregnancy, also known as the "mask of pregnancy" or melasma, in which blotches of pale brown skin appear on the face. It is usually caused by hormonal changes. The blotches may appear in the forehead, cheeks, and nose, and may merge into one dark mask. It usually fades gradually after pregnancy, but it may become permanent or recur with subsequent pregnancies. Some women may also find that the line running from the top to the bottom of their abdomen darkens. This is called the linea nigra.

CHLOROQUINE. An antimalarial drug that was first used in the 1940s, until the first evidence of quinine resistance appeared in the 1960s. It is now ineffective against falciparum malaria almost everywhere. However, because it is inexpensive, it is still the antimalarial drug most widely used in Africa. Native individuals with partial immunity may have better results with chloroquine than a traveler with no previous exposure.

CHOLANGIOGRAPHY. Radiographic examination of the bile ducts after injection with a special dye. It is used to determine whether the bile ducts are enlarged, narrowed, or blocked.

CHOLANGITIS. Infection or inflammation of the bile ducts; often causes abdominal pain, fever, and jaundice.

CHOLECYSTECTOMY. Surgical removal of the gallbladder.

CHOLECYSTITIS. Infection and inflammation of the gallbladder, causing severe pain and rigidity in the upper right abdomen.

CHOLECYSTOTOMY. An operation during which the gallbladder is opened, gallstones are removed, and excess bile is drained. The gallbladder is not removed.

CHOLEDOCHOLITHIASIS. The presence of gallstones within the common bile duct.

CHOLELITHIASIS. Also known as gallstones, these hard masses are formed in the gallbladder or passages, and can cause severe upper right abdominal pain radiating to the right shoulder, as a result of blocked bile flow.

CHOLELITHOTOMY. Surgical incision into the gallbladder to remove stones.

CHOLERA. An infection of the small intestine caused by a type of bacterium. The disease is spread by drinking water or eating seafood or other foods that have been contaminated with the feces of infected people. It occurs in parts of Asia, Africa, Latin America, India, and the Middle East. Symptoms include watery diarrhea and exhaustion and are often fatal to young children and the elderly.

CHOLESCINTIGRAPHY. Another term for a gallbladder nuclear medicine scan.

CHOLESTASIS. A blockage in the flow of bile.

CHOLESTEATOMA. A cystic mass of cells in the middle ear, occurring as a congenital defect or as a serious complication of a disease or traumatic condition of the ear.

CHOLESTEROL. A waxy substance made by the liver and also acquired through diet. High levels in the blood may increase the risk of cardiovascular disease.

CHOLESTEROLOSIS. Cholesterol crystals or deposits in the lining of the gallbladder.

CHOLINERGIC DRUG. A medication that mimics or enhances the action of the neurotransmitter acetylcholine.

CHOLINERGIC NERVES. Nerves that are stimulated by acetylcholine.

CHOLINESTERASE INHIBITORS. Drugs that may slow the progression of AD by inhibiting the enzymes that break down acetylcholine.

CHOREA. A term that is used to refer to rapid, jerky, involuntary movements of the limbs or face that characterize several different disorders of the nervous system, including chorea of pregnancy and Huntington's chorea as well as Sydenham's chorea.

CHORION. The outer embryonic membrane of the developing fetus that gives rise to the placenta. Inside the chorion is the amniotic sac or sacs, inside of which are the fetuses.

CHORIONIC VILLI. Microscopic, finger-like projections that emerge from the outer sac which surrounds the developing baby. Chorionic villi are of fetal origin and eventually form the placenta.

CHORIONIC VILLUS SAMPLING (CVS). A procedure used for prenatal diagnosis at 10–12 weeks gestation. Under ultrasound guidance a needle is inserted either through the mother's vagina or abdominal wall and a sample of cells is collected from around the early embryo. These cells are then tested for chromosome abnormalities or other genetic diseases.

CHOROID. The part of the uveal tract behind the ciliary body. The choroid underlies and nourishes the retina and absorbs scattered light.

CHROMATOGRAPHY. A family of laboratory techniques that separate mixtures of chemicals into their individual components.

CHROMOSOME. A microscopic thread-like structure found within each cell of the body and consists of a complex of proteins and DNA. Humans have 46 chromosomes arranged into 23 pairs. Changes in either the total number of chromosomes or their shape and size (structure) may lead to physical or mental abnormalities.

CHRONIC. Long-term or frequently recurring.

CHRONIC BRONCHITIS. A smoking-related respiratory illness in which the membranes that line the bronchi, or the lung's air passages, narrow over time. Symptoms include a morning cough that brings up phlegm, breathlessness, and wheezing.

CHRONIC DISEASE. An illness or medical condition that lasts over a long period of time and sometimes causes a long-term change in the body.

CHRONIC EXERTIONAL COMPARTMENT SYNDROME (CECS). Compartment syndrome that develops during exercise and subsides when the activity is halted.

CHRONIC HEPATITIS. Long lasting inflammation of the liver due to viruses or other causes.

CHRONIC KIDNEY FAILURE. End-stage renal disease (ESRD); chronic kidney failure is diagnosed as ESRD when kidney function falls to 5–10% of capacity.

CHRONIC LYME DISEASE (CLD). Persistent Lyme disease, post-treatment Lyme disease, or post-Lyme disease syndrome; a controversial diagnosis for various symptoms, including arthritis and neurologic problems, with or without evidence of current or past *B. burgdorferi* infection.

CHRONIC LYMPHOCYTIC LEUKEMIA. A cancer of the blood cells characterized by large numbers of cancerous, mature white blood cells and enlarged lymph nodes.

CHRONIC MYELOGENOUS LEUKEMIA (CML). Also called chronic myelocytic leukemia, a malignant disorder that involves abnormal accumulation of white cells in the marrow and bloodstream.

CHRONIC OBSTRUCTIVE LUNG DISEASE. A common form of lung disease in which breathing, and therefore gas exchange, is labored and increasingly difficult.

CHRONIC OBSTRUCTIVE PULMONARY DISEASE (COPD). A term used to describe chronic lung diseases, like chronic bronchitis, emphysema, and asthma.

CHRONIC OTITIS MEDIA. Inflammation of the middle ear with signs of infection lasting three months or longer.

CHRONIC PAIN. Pain that lasts more than three months and threatens to disrupt daily life.

CHRONIC RENAL (KIDNEY) FAILURE. Progressive loss of kidney function over several years that can result in permanent kidney failure requiring dialysis.

CHYMOPAPAIN. An enzyme from the milky white fluid of the papaya, used for medical purposes in chemonucleolysis.

CILIA. Tiny hairlike projections on certain cells within the body; cilia produce lashing or whipping movements to direct or cause motion of substances or fluids within the body.

CILIARY BODY. The part of the uveal tract between the iris and the choroid.

CILIARY MUSCLES. The small muscles that permit the lens to change its shape in order to focus on near or distant objects.

CILIATED. Covered with short, hairlike protrusions, like *B. coli* and certain other protozoa. The cilia or hairs help the organism to move.

WWW.BOOKBAZ.IR

CIRCADIAN. Pertaining to biological rhythms occurring at approximately 24-hour intervals. Jet lag is caused by a disruption of the human body's circadian clock.

CIRCADIAN RHYTHM. Any biological rhythm that originates within an organism and has a time pattern of about 24 hours. In humans, the term is often used to describe the sleep/wake cycle.

CIRCULATION. The passage of blood and delivery of oxygen through the veins and arteries of the body.

CIRCUMCISION. A procedure, usually with religious or cultural significance, in which the prepuce—the skin covering the tip of the male penis or the female clitoris—is cut away.

CIRRHOSIS. A condition characterized by the destruction of healthy liver tissue. A cirrhotic liver is scarred and cannot break down the proteins in the bloodstream. Cirrhosis is associated with portal hypertension.

CITALOPRAM HYDROBROMIDE. An SSRI that is highly specific for serotonin reuptake.

CLASSIC KAPOSI'S SARCOMA. A form of KS that usually affects older men of Mediterranean or eastern European backgrounds and produces tumors on the lower legs.

CLASSICAL INCISION. A vertical incision of the uterus during cesarean delivery.

CLAUDICATION. Attacks of lameness or pain chiefly in the calf muscles, brought on by walking because of a lack of oxygen reaching the muscle.

CLEAN-CATCH SPECIMEN. A urine specimen that is collected from the middle of the urine stream after the first part of the flow has been discarded.

CLEFT PALATE. A congenital malformation in which there is an abnormal opening in the roof of the mouth that allows the nasal passages and the mouth to be improperly connected.

CLINDAMYCIN. An antibiotic that can be used instead of penicillin.

CLINICAL AROMATHERAPY. Aromatherapy is the therapeutic use of plant-derived, aromatic essential oils to promote physical and psychological well-being. It is sometimes used in combination with massage and other therapeutic techniques as part of a holistic treatment approach.

CLINICAL BREAST EXAM (CBE). An examination performed by a healthcare provider to detect lumps or other irregularities in the breasts.

CLINICAL NUTRITION. The use of diet and nutritional supplements as a way to enhance health and prevent disease.

CLINICAL TRIAL. All new drugs undergo clinical trials before approval. Clinical trials are carefully conducted tests in which effectiveness and side effects are studied, with the placebo effect eliminated.

CLINICALLY DYSFUNCTIONAL ANGER. Anger that is ongoing, also called chronic, or excessive. The anger usually is expressed in ways that harm the person or others around the person, such as with overly emotional, hostile, threatening, or violent reactions.

CLITORIDECTOMY. A procedure in which the clitoris and possibly some of the surrounding labial tissue at the opening of the vagina is removed.

CLITORIS. The small erectile organ at the front of the female vulva that is the site of female sexual pleasure.

CLONIC. Referring to clonus, rapid contractions and relaxations of a muscle.

CLOSED-HEAD INJURY. An injury to the head in which the skull is not broken or penetrated.

CLOSTRIDIUM PERFRINGENS. A bacterium that is a common cause of food poisoning.

CLOT. A soft, semisolid mass that forms when blood gels.

CLOTTING FACTOR. Also known as coagulation factors. Proteins in the plasma that serve to activate various parts of the blood clotting process by being transformed from inactive to active form.

CLUBBING. Clubbing is the rounding of the ends and swelling of fingers found in people with lung disease.

COAGULATION. The process of blood clotting.

COAGULATION CASCADE. The sequence of biochemical activities, involving clotting factors, that stop bleeding by forming a clot.

COAGULATION FACTORS. Proteins in the plasma that serve to activate various parts of the blood clotting process by being transformed from inactive to active form.

COAGULOPATHY. A disorder in which blood is either too slow or too quick to coagulate (clot).

COARCTATION. The medical term for a constriction or narrowing.

COARCTATION OF THE AORTA. A congenital defect in which severe narrowing or constriction of the aorta obstructs the flow of blood.

COBB ANGLE. A measure of the curvature of scoliosis, determined by measurements made on x rays.

COCCOBACILLUS (PLURAL, COCCOBACILLI). A short rod-shaped bacterium. *Listeria* species are coccobacilli.

COCCYDYNIA. Also called coccygodynia. Pain in or around the coccyx.

COCCYX. The last bone of the spinal column, consisting of three to five fused vertebrae that connect with the sacrum, a part of the pelvis.

COCHLEA. The hearing part of the inner ear. This snail-shaped structure contains fluid and thousands of microscopic hair cells tuned to various frequencies.

CODEINE. A morphine derivative that is found in opium or synthesized; it is milder than morphine and is prescribed for pain relief and coughs.

COENZYME. Also called a cofactor; a small nonprotein molecule that binds to an enzyme and catalyzes (stimulates) enzyme-mediated reactions.

COGNITION. The mental activities associated with thinking, learning, and memory.

COGNITIVE BEHAVIORAL THERAPY (CBT). A type of psychotherapy in which people learn to recognize and change negative and self-defeating patterns of thinking and behavior.

COGNITIVE PROCESSES. Thought processes (e.g., reasoning, perception, judgment, memory).

COGNITIVE PROCESSING THERAPY. A term that is sometimes used for the cognitive restructuring aspect of cognitive-behavioral therapy as it is applied to treatment for PTSD.

COGNITIVE RESTRUCTURING. The process of replacing maladaptive thought patterns with constructive thoughts and beliefs.

COGNITIVE THERAPY. A form of short-;term psychotherapy that focuses on changing people's patterns of emotional reaction by correcting distorted patterns of thinking and perception.

COINFECTION. Invasion of the body by two viruses at about the same time.

COITUS. Sexual intercourse.

COLCHICINE. A compound that blocks the assembly of microtubules–protein fibers necessary for cell division and some kinds of cell movements, including neutrophil migration. Side effects may include diarrhea, abdominal bloating, and gas.

COLD AGGLUTININS. Antibodies that cause clumping of red blood cells when the blood temperature falls below normal body temperature (98.6°F/37°C).

COLD SORE. A small blister on the lips or face, caused by a virus. Also called a fever blister.

COLD TURKEY. A slang term for stopping the use of nicotine (or any other addictive drug) suddenly and completely.

COLECTOMY. The surgical removal of the colon or part of the colon.

COLITIS. Inflammation of the colon (large bowel).

COLLAGEN. The main supportive protein of cartilage, connective tissue, tendon, skin, and bone.

COLLAGEN-VASCULAR DISEASE. Various diseases inflaming and destroying connective tissue.

COLLATERAL VESSEL. A side branch or network of side branches of a large blood vessel.

COLLATERALS. Alternate pathways for arterial blood.

COLON. The part of the large intestine that lies between the cecum and the rectum. It is responsible for forming, storing and expelling waste matter.

COLONIZATION. The presence of bacteria on a body surface (like on the skin, mouth, intestines, or airway) without causing disease in the person.

COLONIZE. To become established in a host.

COLONIZED. This occurs when a microorganism is found on or in a person without causing a disease.

COLONOSCOPE. A thin, flexible, hollow, lighted tube that is inserted through the anus and rectum into the colon to enable the physician to view the entire lining of the colon.

COLONOSCOPY. A procedure in which the colon is cleansed and the a lighted fiber-optic instrument is inserted through the anus to allow the physician to view the entire length of the colon and detect abnormalities in the colon lining, including polyps and ulcers.

COLORECTAL CANCER. Cancer of the large intestine, or colon, including the rectum.

WWW.BOOKBAZ.IR

COLOSTOMY. An operation where the large intestine is diverted through an opening in the abdomen and waste is excreted.

COLPOSCOPE. An instrument used for examination of the vagina and cervix. Part of the instrument includes a magnifying lens for better visualization.

COLPOSCOPY. Diagnostic procedure using a hollow, lighted tube (colposcope) to look inside the cervix and uterus.

COLUMELLA. The strip of skin running from the tip of the nose to the upper lip, which separates the nostrils.

COMA. A condition of deep unconsciousness from which the person cannot be aroused.

COMBAT MEDIC. A soldier, sailor, or airman who is not a medical doctor but has received basic EMT training and is responsible for providing first aid and frontline trauma care on the battlefield.

COMBAT STRESS REACTION. A general term for mental health symptoms that include depression, fatigue, dissociative symptoms, difficulty focusing, and irritability. It is not identical to PTSD but may be a precursor of it. The condition was sometimes referred to as "combat fatigue" in World War II.

COMEDO, COMEDONE. A hard plug composed of sebum and dead skin cells.

COMEDOLYTIC. A drug that breaks up comedones and opens clogged pores.

COMMAND HALLUCINATIONS. Hallucinations, usually auditory, in which a person is commanded to commit an act such as suicide.

COMMENSALISM. A close, long-term relationship between two organisms, in which one organism receives a benefit from the relationship, and the other organism is neither benefited nor harmed by it.

COMMINUTED FRACTURE. A fracture where there are several breaks in a bone creating numerous fragments.

COMMON BILE DUCT. The passage through which bile travels from the cystic duct to the small intestine.

COMMON COLD. A mild illness caused by a upper respiratory viruses. Usual symptoms include nasal congestion, coughing, sneezing, throat irritation, and a low-grade fever.

COMMON PATHWAY. The pathway that results from the merging of the extrinsic and intrinsic pathways. The common pathway includes the final steps before a clot is formed.

COMMUNICABLE. Capable of being transmitted.

COMMUNITY-ACQUIRED. Refers to an infectious disease that is passed among individuals who have close contact with one another.

COMORBID. A term applied to a disease or disorder that occurs at the same time as another disease condition.

COMPARTMENT. A muscle group and its accompanying nerves and blood vessels that are contained within the fascia.

COMPARTMENT SYNDROME. Compartment syndrome is a condition in which a muscle swells but is constricted by the connective tissue around it, which cuts off blood supply to the muscle.

COMPLEMENT. One of several proteins in the blood that acts with other proteins to assist in killing bacteria.

COMPLEMENTARY. Something that serves to fill out or complete something else.

COMPLEMENTARY MEDICINE. A nonconventional therapy that is used together with or alongside mainstream treatment.

COMPLETE BLOOD COUNT (CBC). A blood test to check the numbers of red blood cells, white blood cells, and platelets in the blood.

COMPLETE DENTURE. A full set of upper or lower teeth, mounted in a plastic base. Dentures are also called false teeth.

COMPLEX CARBOHYDRATES. Polysaccharides, such as starch, made up of hundreds or thousands of sugar units and found in foods such as rice, whole grains, and pasta, as well as fruits and vegetables.

COMPLEX REGIONAL PAIN SYNDROME (CRPS). Severe, chronic, often burning pain in an extremity, typically occurring after an injury and accompanied by various other symptoms.

COMPLIANCE. A term used to describe how well a patient's behavior follows medical advice.

COMPLICATED GRIEF. An abnormal response to bereavement that includes unrelieved yearning for the dead person, the complete loss of previous positive beliefs or worldviews, and a general inability to function.

COMPOSITE FILLING. A resin material that is tooth colored and is used to fill a tooth once decay has been removed. It is used most often in front teeth, but may be used in any tooth for aesthetic reasons.

COMPOSITE RESIN. Plastic material matching natural tooth color used to replace missing parts of a tooth.

COMPOSITE TISSUE ALLOTRANSPLANTATION (CTA). Transplantation of a functional unit made up of different tissues, such as a hand or face.

COMPOUND FRACTURE. A fracture in which the broken end or ends of the bone have penetrated through the skin; also known as an open fracture.

COMPOUND HETEROZYGOTES. Individuals who have one gene in a pair with one mutation and the other gene in the pair has a different mutation.

COMPRESSED AIR. Air that is held under pressure in a tank to be breathed underwater by divers. A tank of compressed air is part of a diver's scuba (self-contained underwater breathing apparatus) gear.

COMPRESSION. An increase in pressure from the surrounding water that occurs with increasing diving depth.

COMPRESSION FRACTURE. A fracture caused by the collapse of a vertebra in the spinal column, usually caused either by trauma or by weakening of the bone in osteoporosis.

COMPULSION. A repetitive or ritualistic behavior that a person performs to reduce anxiety. Compulsions often develop as a way of controlling or undoing obsessive thoughts.

COMPULSIVE GAMBLING DISORDER. An impulse control disorder in which an individual cannot resist gambling despite repeated losses.

COMPUTED TOMOGRAPHY (CT OR CAT) SCAN. A radiologic imaging modality that uses computer processing to generate an image of the tissue density in a "slice" as thin as 1–10 mm in thickness through the patient's body. These images are spaced at intervals of 0.5–1 cm. Cross-sectional anatomy can be reconstructed in several planes without exposing the patient to additional radiation. Also called computerized axial tomography (CAT) and computerized transaxial tomography (CTAT).

COMT INHIBITORS. Drugs that block catechol-o-methyl transferase, an enzyme that breaks down dopamine. COMT inhibitors include entacapone and tolcapone.

CONCENTRATION. Refers to the amount of solute present in a solution, compared to the total amount of solvent.

CONCEPTION. The union of egg and sperm to form a fetus.

CONCUSSION. Injury to the brain causing a sudden but temporary impairment of brain function.

CONDITIONING. Process of preparing a patient to receive marrow donation, often through the use of chemotherapy and radiation therapy.

CONDOM. A thin sheath worn over the penis during sexual intercourse to prevent pregnancy or the transmission of STIs. There are also condoms for females to wear in the vagina.

CONDUCT DISORDER. A behavioral and emotional disorder of childhood and adolescence. Children with such a disorder act inappropriately, infringe on the rights of others, and violate societal norms.

CONDUCTION APHASIA. A condition characterized by the inability to repeat words, sentences, or phrases as a result of a stroke, head injury, brain tumor, or infection.

CONDUCTIVE HEARING LOSS. A type of medically treatable hearing loss in which the inner ear is usually normal but there are specific problems in the middle or outer ears that prevent sound from getting to the inner ear in a normal way.

CONDYLOMATA ACUMINATA. Another term for genital warts.

CONDYLOMATA LATA. Highly infectious patches of weepy, pink or gray skin in moist areas of the body that occur during secondary syphilis.

CONES. Receptor cells that allow the perception of colors.

CONFABULATION. An attempt to fill in memory gaps by fabricating information or details.

CONGENITAL. A condition that is present at birth.

CONGENITAL ADRENAL HYPERPLASIA. A hormonal disorder among women of reproductive age in which the ovaries tend to be enlarged and contain numerous small cysts along the outer edge of each ovary.

CONGENITAL CYSTIC ADENOMATOID MALFORMATION (CCAM). A condition in which one or more lobes of the fetal lungs develop into fluid-filled sacs called cysts.

CONGENITAL DIAPHRAGMATIC HERNIA (CDH). A condition in which the fetal diaphragm—the muscle dividing the chest and abdominal cavity—does not close completely.

WWW.BOOKBAZ.IR

CONGENITAL HEART DEFECTS. Abnormal formation of structures of the heart or of its major blood vessels present at birth.

CONGESTIVE CARDIOMYOPATHY. Also called dilated cardiomyopathy; cardiomyopathy in which the walls of the heart chambers stretch, enlarging the heart ventricles so they can hold a greater volume of blood than normal.

CONGESTIVE HEART FAILURE. A condition in which the heart cannot pump enough blood to supply the body's tissues with sufficient oxygen and nutrients; back up of blood in vessels and the lungs causes buildup of fluid (congestion) in the tissues.

CONIZATION. Cone biopsy; removal of a cone-shaped section of tissue from the cervix for diagnosis or treatment.

CONJUNCTIVA. The mucous membrane that covers the white part of the eyes (sclera) and lines the eyelids.

CONJUNCTIVITIS. Inflammation of the conjunctiva, the mucous membrane lining the inner surfaces of the eyelid and the front of the eyeball.

CONN'S SYNDROME. A disorder caused by excessive aldosterone secretion by a benign tumor of one of the adrenal glands. This results in malfunction of the body's salt and water balance and subsequently causes hypertension. Symptoms include thirst, muscle weakness, and excessive urination.

CONNECTIVE TISSUE. A group of tissues responsible for support throughout the body; includes cartilage, bone, fat, tissue underlying skin, and tissues that support organs, blood vessels, and nerves throughout the body.

CONSANGUNITY. Related from a common ancestor; blood relative.

CONSCIOUS SEDATION. A level of sedation during which the patient remains awake but very relaxed.

CONSERVATOR. Legal guardian.

CONSOLIDATION. A condition in which lung tissue becomes firm and solid rather than elastic and air-filled because it has accumulated fluids and tissue debris.

CONSTIPATION. Abnormally delayed or infrequent passage of feces. It may be either functional (related to failure to move the bowels) or organic (caused by another disease or disorder).

CONSUMER OPERATED AND ORIENTED PLANS (CO-OPS). Independent, nonprofit, member-owned, and member-operated health insurance companies established under the PPACA.

CONTACT DERMATITIS. Skin inflammation from contact with an allergen or other irritating substance.

CONTAMINATION. The process by which an object or body part becomes exposed to an infectious agent such as a virus.

CONTINENCE. The ability to control one's bladder and bowel functions.

CONTINUITY. Uninterrupted and successive.

CONTINUOUS POSITIVE AIRWAY PRESSURE (CPAP). A ventilation system that blows a gentle stream of air into the nose to keep the airway open.

CONTRACEPTION. The use of a device, sexual practice, or chemical intended to prevent conception; birth control. It should not be confused with safe sex.

CONTRACTION. A tightening of the uterus during pregnancy. Contractions may or may not be painful and may or may not indicate labor.

CONTRACTURE. A tightening of muscles that prevents normal movement of the associated limb or other body part.

CONTRAST (AGENT, MEDIUM). A substance injected into the body that outlines certain structures that would otherwise be hard to see on a radiograph (film).

CONTRAST HYDROTHERAPY. A series of hot and cold water applications. A hot compress (as hot as an individual can tolerate) is applied for three minutes followed by an ice cold compress for 30 seconds. These applications are repeated three times each and ending with the cold compress.

CONTRAST MEDIUM. A chemical or other substance placed in the body to show structures that would not otherwise be visible on x ray or other imaging studies.

CONTRAST SOLUTION. A chemical or other substance placed in the body to show structures that would not otherwise be visible on x ray or other imaging studies.

CONTRECOUP. An injury to the brain opposite the point of direct impact.

CONTUSION. A focal area of swollen and bleeding brain tissue.

CONVENTIONAL THERAPY. Treatments that are widely accepted and practiced by the mainstream medical community.

CONVERSION DISORDER. A somatoform disorder characterized by the transformation of a psychological feeling or impulse into a physical symptom. Conversion disorder was previously called hysterical neurosis, conversion type.

CONVULSION. Involuntary contractions of body muscles that accompany a seizure episode.

COOLEY'S ANEMIA. Another name for the most severe form of beta-thalassemia. It is named for Thomas Benton Cooley (1871–1945), an American pediatrician who first described it in the children of Italian immigrants.

CO-PAYMENT. The amount that an insured individual pays out-of-pocket for healthcare services.

COPING. In psychology, a term that refers to a person's patterns of response to stress. Some patterns of coping may lower a person's risk of developing Stockholm syndrome in a hostage situation.

COPROLALIA. The involuntary expression of obscene words or phrases.

COPROPRAXIA. The involuntary display of unacceptable/obscene gestures.

COR PULMONALE. Enlargement of the right ventricle of the heart caused by pulmonary hypertension that may result from emphysema or bronchiectasis; eventually, the condition leads to congestive heart failure.

CORDOCENTESIS. A procedure for delivering a blood transfusion to a fetus. It involves a fine needle being threaded through a pregnant woman's abdomen and into the umbilical cord with the aid of ultrasound imaging.

CORNEA. The clear, dome-shaped part of the front of the eye, through which light first enters the eye. It is located in front of the colored part of the eye (iris).

CORNEAL ABRASION. A scratch on the surface of the eyeball.

CORNEAL TOPOGRAPHY. Mapping the cornea's surface with a specialized computer that illustrates corneal elevations.

CORONARY. Of or relating to the heart.

CORONARY ARTERIES. These are the first arteries to branch off the aorta (the large artery leaving the heart). The coronary arteries surround the heart like a crown, coming out of the aorta, arching down over the top of the heart, dividing into two branches, and taking oxygen-rich blood to the heart muscle. Blockage of these arteries can cause atherosclerosis and heart attack.

CORONARY ARTERY BYPASS. Surgical procedure to reroute blood around a blocked coronary artery.

CORONARY ARTERY DISEASE. Also called atherosclerosis, it is a chronic condition characterized by thickening and hardening of the arteries and the buildup of plaque on the arterial walls. It can slow or impair blood circulation.

CORONARY BLOOD VESSELS. The arteries and veins that supply blood to the heart muscle.

CORONARY BYPASS SURGERY. A surgical procedure that places a shunt to allow blood to travel from the aorta to a branch of the coronary artery at a point below an obstruction.

CORONARY OCCLUSIVE ARTERY DISEASE. Blockage of the arteries that supply blood to the heart, frequently a precursor to a heart attack.

CORONAVIRUS. A genus of viruses that cause respiratory disease and gastroenteritis.

CORONER. A public officer who determines (in some cases with the help of a jury) the cause of any death not obviously due to natural causes; certifies the death for the public record; and may proceed with an investigation. The name comes from the Latin word for crown, because the English coroner was originally an officer of the Crown.

CORPORA CAVERNOSA. The pair of columns of erectile tissue on either side of the penis that, together with the corpus spongiosum, produce an erection when filled with blood.

CORPUS LUTEUM. A small, yellow structure that forms in the ovary after an egg has been released.

CORTEX. The thin, convoluted surface of the brain comprised primarily of cell bodies of neurons.

CORTICAL. Regarding the cortex, or the outer layer of the brain, as distinguished from the inner portion.

CORTICOSTERIOD. A group of hormones produced naturally by the adrenal gland or manufactured synthetically. They are often used to treat inflammation. Examples include cortisone and prednisone.

CORTISOL. A hormone secreted by the cortex of the adrenal gland. Cortisol regulates the function of nearly every organ and tissue in the body.

WWW.BOOKBAZ.IR

CORTISONE. A glucocorticoid compound produced by the adrenal cortex in response to stress. Cortisone is a steroid with anti-inflammatory and immunosuppressive properties.

CO-SLEEPING. Allowing a baby to sleep in the same bed as its parents. It is also called bed sharing.

COSMESIS (PLURAL, COSMESES). A prosthesis designed to look as lifelike as possible.

COUGH SUPPRESSANT. Medicine that stops or prevents coughing.

COUGHING. Coughing helps break up secretions in the lungs so that the mucus can be suctioned out or expectorated. Patients sit upright and inhale deeply through the nose. They then exhale in short puffs or coughs. Coughing is repeated several times per day.

COUNTERTRANSFERENCE. The analyst's emotional reaction to or entanglement with the analysand.

COWPOX. A mild disease in cows that is caused by a poxvirus.

COX-2 INHIBITORS. A class of newer nonsteroidal anti-inflammatory drugs (NSAIDs) that are less likely to cause side effects in the digestive tract. COX-2 inhibitors work by inhibiting the production of cyclooxygenase-2, an enzyme involved in inflammation.

COXSACKIE B VIRUS. A type of virus in the group Enterovirus that causes an infection similar to polio, but without paralysis.

CRABS. An informal term for pubic lice.

CRANIAL NERVES. The set of 12 nerves found on each side of the head and neck that control the sensory and muscle functions of a number of organs such as the eyes, nose, tongue, face, and throat.

CRANIOCAUDAL. Head-to-tail x-ray beam directly overhead the part being examined.

CRANIOFACIAL SURGERY. Surgery of the facial tissue and skull.

CRANIOPHARYNGEAL ACHALASIA. A swallowing disorder of the throat.

CRANIOPHARYNGIOMA. A tumor near the pituitary gland in the craniopharyngeal canal that often results in intracranial pressure.

CRANIOSYNOSTOSIS. A premature closure of one or more of the joints (fissures) between the bones of the skull, which causes an abnormally shaped skull.

CRANIOTOME. A type of surgical drill used to operate on the skull. It has a self-controlled system that stops the drill when the bone is penetrated.

CRANIOTOMY. Procedure to remove a lesion in the brain through an opening in the skull.

C-REACTIVE PROTEIN (CRP). A protein in the blood that indicates inflammation.

CREAM. A spreadable substance, similar to an ointment, but not as thick. Creams may be more appropriate than ointments for application to exposed skin areas such as the face and hands.

CREATINE. Creatine is a substance produced from protein and stored in the muscles. Creatine is a source for energy, allowing muscle contraction to take place. Some creatine is converted to creatinine, and enters the bloodstream, where it is filtered out by healthy kidneys and leaves the body in the urine. When the kidneys are not functioning properly, creatinine levels in the blood become abnormally elevated.

CREATINE KINASE. Creatine phosphokinase (CPK); any of three similar enzymes (isozymes) involved in energy transfer in skeletal muscle and released into the blood with muscle injury.

CREATININE. The metabolized by-product of creatine, an organic compound that assists the body in producing muscle contractions. Creatinine is found in the bloodstream and in muscle tissue. It is removed from the blood by the kidneys and excreted in the urine.

CREATININE CLEARANCE RATE. The clearance of creatinine from the plasma compared to its appearance in the urine. Since there is no reabsorption of creatinine, this measurement can estimate glomerular filtration rate.

CREEPING ERUPTION. Itchy irregular, wandering red lines on the foot made by burrowing larvae of the hookworm family and some roundworms.

CREMASTERIC REFLEX. A reflex in which the cremaster muscle, which covers the testes and the spermatic cord, pulls the testicles back into the scrotum. It is important for a doctor to distinguish between an undescended testicle and a hyperactive cremasteric reflex in small children.

CREPITUS. A crackling sound.

CRETINISM. Severe hypothyroidism that is present at birth and characterized by severe intellectual disability.

CREUTZFELDT-JAKOB DISEASE. A degenerative disease of the central nervous system caused by a prion, or "slow virus."

CRIB DEATH. Another name for SIDS. It is often called cot death in the United Kingdom, Australia, and New Zealand.

CRIBRIFORM PLATE. The horizontal bone plate perforated with several holes for the passage of olfactory nerve filaments from the nasal cavity.

CRICOTHYROIDOTOMY. An emergency tracheotomy that consists of a cut through the cricothyroid membrane to open the patient's airway as fast as possible.

CRIGLER-NAJJAR SYNDROME. A moderate to severe form of hereditary jaundice.

CRIMINALISTICS. A general term for various analytical techniques used in crime investigations, such as fingerprint and trace evidence analysis, tire track and footprint analysis, ballistics, toolmark examination, and others.

CROHN'S DISEASE. A chronic inflammatory disease that generally starts in the gastrointestinal tract and causes the immune system to attack one's own body.

CROSSBITE. The condition in which the upper teeth bite inside the lower teeth.

CROSS-DRESSING. Wearing clothes and other accessories associated with the opposite sex in one's particular society.

CROSSMATCH. A test to determine whether patient and donor tissues are compatible.

CROSS-REACTION. A reaction that occurs in blood testing when a disease agent reacts to the specific antibody for another disease agent.

CROSS-TOLERANT. A drug that has the same pharmacological effect as another is considered cross-tolerant. Cross-tolerant drugs are often used in treating withdrawal syndromes.

CROWN. The upper part of the tooth, covered by enamel; also, a dental restoration that is a protective shell fitting over a tooth.

CRYOABLATION. A technique for removing tissue by destroying it with extreme cold.

CRYOGEN. A substance with a very low boiling point, such as liquid nitrogen, used in cryotherapy treatment.

CRYOGLOBULIN. An abnormal blood protein associated with several diseases. It is characterized by its tendency to clump in cold temperatures.

CRYOGLOBULINEMIA. Condition in which protein in the blood forms particles in the cold, blocking blood vessels, leading to pain and numbness of the extremities.

CRYOSURGERY. The use of extreme cold to kill or remove tissue.

CRYOTHERAPY. The use of extreme cold to kill or remove tissue.

CRYPTORCHIDISM. A developmental disorder in which one or both testes fail to descend from the abdomen into the scrotum before birth. It is the most common structural abnormality in the male genital tract.

CRYPTOSPORIDIUM. A type of parasitic protozoa.

CUE. In psychology, a sensory stimulus or signal that can be extracted or distinguished from surrounding stimuli by a perceiver.

CULTURAL CLIMATE. The political and social environment of an institution or a society.

CULTURE. A laboratory procedure in which a sample from a wound, the blood or other body fluid is taken from an infected person. The sample is placed in conditions under which bacteria can grow. If bacteria grow, identification tests are done to determine the bacteria species causing the infection.

CULTURING. To grow cells in a special substance, or media, in the laboratory.

CUPPING. This consists of rhythmically striking the chest wall with cupped hands. The purpose of percussion is to break up thick secretions in the lungs so that they can be more easily removed. Percussion is performed on each lung segment for one to two minutes at a time.

CURET. A surgical instrument with a circular cutting loop at one end. The curet is pulled over the skin lesion in repeated strokes to remove one portion of the lesion at a time.

CURETTAGE. The removal of tissue or growths by scraping with a curette.

CURETTE. Spoon-shaped instrument for removing debris, growths, or infected nail matter.

CUSHING'S SYNDROME. A hormonal disorder caused by an abnormally high level of corticosteroid hormones that are produced by the adrenal glands.

WWW.BOOKBAZ.IR

Corticosteroid hormones control the body's use of nutrients and the excretion of salts and water in the urine. Symptoms include high blood sugar levels, a moon face, weight gain, and increased blood pressure.

CUT. Separation of skin or other tissue made by a sharp edge, producing regular edges.

CUTANEOUS. Pertaining to the skin

CYANOSIS. Blue, gray, or dark purple discoloration of the skin caused by a deficiency of oxygen.

CYANOTIC. Blue, gray, or dark purple discoloration of the skin caused by a deficiency of oxygen.

CYCLIC VOMITING SYNDROME (CVS). Episodes of severe nausea, gagging, and vomiting in children that last for hours or a day or two, repeat at regular intervals, and have no known cause.

CYCLICAL NEUTROPENIA. A rare genetic blood disorder in which the patient's neutrophil level drops below $500/mm^3$ for six to eight days every three weeks.

CYCLOTHYMIA. A milder form of bipolar disorder characterized by alternating hypomania and less severe depressive episodes.

CYST. A liquid-filled structure developing abnormally in the body.

RADICAL CYSTECTOMY. Surgical removal of the bladder.

CYSTECTOMY. Surgical removal of a cyst.

CYSTIC ARTERY. An artery that brings oxygenated blood to the gallbladder.

CYSTIC FIBROSIS. A genetic disease that causes multiple digestive, excretion, and respiratory complications. Among the effects, the pancreas fails to provide secretions needed for the digestion of food.

CYSTIC FIBROSIS TRANSMEMBRANE CONDUCTANCE REGULATOR (CFTR). The protein responsible for regulating chloride movement across cells in some tissues. When a person has two defective copies of the CFTR gene, cystic fibrosis is the result.

CYSTICERCOSIS. Parasitic infection caused by the presence of immature tapeworm larvae (cysticerci) that have developed outside the intestinal tract. Infection is caused by accidental consumption of tapeworm eggs.

CYSTINE. An amino acid normally reabsorbed by the kidney tubules. Cystinuria is an inherited disease in which cystine and some other amino acids are not reabsorbed by the body in normal amounts. Cystine crystals then form in the kidney, which leads to obstructive renal failure.

CYSTINOSIS. A genetic disorder characterized by a buildup of an amino acid called cystine in the body. It leads to abnormal amounts of carbohydrates and amino acids in the urine, excessive urination, and low blood levels of potassium and phosphates.

CYSTITIS. Inflammation of the bladder, usually caused by bacterial infection.

CYSTOCELE. Bulging of the bladder into the vagina.

CYSTOMETRY. A test of bladder function in which pressure and volume of fluid in the bladder are measured during filling, storage, and voiding.

CYSTOSCOPE. Endoscope especially designed for urological use to examine the bladder, lower urinary tract, and prostate gland.

CYSTOSCOPY. A diagnostic procedure that uses a cystoscope to look inside the bladder and to collect samples of urine and tissue.

CYSTOTOMY. An incision in the bladder.

CYSTOURETHROCELE. Bulging of the bladder neck into the vagina.

CYTOCHROME. A substance that contains iron and acts as a hydrogen carrier for the eventual release of energy in aerobic respiration.

CYTOGENETICS. A class of proteins, including interleukins, that are released by cells to regulate the length and intensity of an immune response and mediate intercellular communication.

CYTOKINES. A class of proteins, including interleukins, that are released by cells to regulate the length and intensity of an immune response and mediate intercellular communication.

CYTOMEGALOVIRUS (CMV). A common human virus causing mild or no symptoms in healthy people, but permanent damage or death to an infected fetus, a transplant patient, or a person with HIV.

CYTOPATHOLOGY. Another name for cytology; the study of cells or cell types.

CYTOPLASM. The part of a cell outside of the nucleus.

CYTOSTATIC DRUG. Any drug that inhibits or prevents cell division and proliferation.

D

DACRON. A synthetic polyester fiber used to surgically repair damaged sections of heart muscle and blood vessel walls.

DACRON GRAFT. A synthetic polyester fiber used to surgically repair damaged sections of heart muscle and blood vessel walls.

DACRYOCYSTOGRAPHY. An x ray of the tear duct after injection of a dye that is used to help locate a blockage in the duct.

DACRYOCYSTORHINOSTOMY. A surgical procedure to drain the tear sac into the nasal passage.

DACRYOSTENOSIS. Obstruction or narrowing of the nasolacrimal duct. May be present at birth.

DARK FIELD. A microscopy technique in which light is directed at an oblique angle so that organisms appear bright against a dark background.

DAWN SIMULATION. A form of light therapy in which the patient is exposed while asleep to gradually brightening white light over a period of an hour and a half.

DEBILITATING. Weakening, or reducing the strength of.

DEBRIDEMENT. Removal of dead and damaged tissue.

DEBULKING. The surgical removal of part of a cancerous tumor that cannot be completely excised, in order to improve the effectiveness of radiation therapy or chemotherapy.

DECELERATION. A decrease in the fetal heart rate that can indicate inadequate blood flow through the placenta.

DECIBEL. A unit of measure for expressing the loudness of a sound. Normal speech is typically spoken in the range of about 20–50 decibels.

DECIDUOUS TEETH. The primary, baby, or milk teeth that fall out and are replaced by permanent teeth.

DECISION TREE. A decision support model used in medical and psychiatric diagnosis that consists of a tree-like chart or diagram including various symptoms, tentative diagnoses, diagnostic decisions, and their possible consequences.

DECOMPRESSION. Surgery, such as disk removal, that relieves pressure on the nerve roots of the spine.

DECOMPRESSION SICKNESS. A condition found in divers in which gas bubbles of nitrogen form in tissues and blood vessels as a result of decreasing surrounding pressure, such as in ascent from a dive. It may be a painful condition, especially as nitrogen bubbles invade the joints; persons stricken may walk stooped over in pain, in a bent stance that led to it being called "the bends."

DECONGESTANT. Medicines that shrink blood vessels and consequently mucus membranes. Pseudoephedrine, phenylephrine, and phenylpropanolamine are the most common.

DECORTICATION. Surgical removal of the fibrous peel that covers the lungs in third-stage empyema.

DECREASED PENETRANCE. Individuals who inherit a changed disease gene but do not develop symptoms.

DECUBITUS ULCERS. A pressure sore resulting from ulceration of the skin occurring in persons confined to bed for long periods of time

DEDUCTIBLE. The amount that an insured person is required to pay on each claim or over the course of a year.

DEEP BITE. A closed bite; a deep or excessive overbite in which the lower incisors bite too closely to or into the gum tissue or palate behind the upper teeth.

DEEP BREATHING. Deep breathing helps expand the lungs and forces better distribution of the air into all sections of the lung. The patient either sits in a chair or sits upright in bed and inhales, pushing the abdomen out to force maximum amounts of air into the lung. The abdomen is then contracted, and the patient exhales. Deep breathing exercises are done several times each day for short periods.

DEEP VEIN THROMBOSIS (DVT). A blood clot in the calf's deep vein. This frequently leads to pulmonary embolism if untreated.

DEFECATE. To pass feces (stool) out of the rectum through the anus.

DEFECATION. Passage of feces through the anus.

DEFERVESCENCE. Return to normal body temperature after high fever.

DEFIBRILLATION. Use of an electric shock to restore a normal heartbeat.

DEFIBRILLATOR. A device that delivers an electric shock to the heart muscle through the chest wall in order to restore a normal heart rate.

WWW.BOOKBAZ.IR

DEFICIENCY. A shortage of something necessary for health.

DEGAS. To release and vent gases. New building materials often give off gases and odors and the air should be well circulated to remove them.

DEGENERATION. Gradual, progressive loss of nerve cells.

DEGENERATIVE. Degenerative disorders involve progressive impairment of both the structure and function of part of the body.

DEGENERATIVE ARTHRITIS, OR OSTEOARTHRITIS. A noninflammatory type of arthritis, usually occurring in older people, characterized by degeneration of cartilage, enlargement of the margins of the bones, and changes in the membranes in the joints.

DEHISCENCE. A premature bursting open or splitting along natural or surgical suture lines. A complication of surgery that occurs secondary to poor wound healing.

DEHYDRATION. A condition in which the body lacks the normal level of fluids, potentially impairing normal body functions.

DELAYED HYPERSENSITIVITY REACTIONS. Allergic reactions mediated by T cells that occur hours to days after exposure to the antigen.

DELETION. The absence of genetic material that is normally found in a chromosome. Often, the genetic material is missing due to an error in replication of an egg or sperm cell.

DELIRIUM. A disturbance of consciousness marked by confusion, inattention, delusions, hallucinations, and agitation. It is distinguished from dementia by its relatively sudden onset and variation in the severity of symptoms.

DELIRIUM TREMENS. A complication that may accompany alcohol withdrawal. The symptoms include body shaking (tremulousness), insomnia, agitation, confusion, hearing voices or seeing images that are not really there (hallucinations), seizures, rapid heartbeat, profuse sweating, high blood pressure, and fever.

DELUSION. A persistent false belief held in the face of strong contradictory evidence.

DELUSIONAL DISORDER. Individuals with delusional disorder suffer from long-term, complex delusions that fall into one of six categories: persecutory, grandiose, jealous, erotomanic, somatic, or mixed.

DEMENTIA. A group of symptoms (syndrome) associated with a chronic progressive impairment of memory, reasoning ability, and other intellectual functions, personality changes, deterioration in personal grooming, and disorientation.

DEMENTIA PUGILISTICA. A term for "punch-drunk" syndrome of brain damage caused by repeated head trauma.

DEMYELINATING DISORDERS. A group of diseases characterized by the breakdown of myelin, the fatty sheath surrounding and insulating nerve fibers. This breakdown interferes with nerve function, and can result in paralysis. Multiple sclerosis is a demyelinating disorder.

DEMYELINATION. Disruption or destruction of the myelin sheath, leaving a bare nerve. Results in a slowing or stopping of impulses traveling along that nerve.

DENDRITES. Fibers of a brain cell that receive signals from other brain cells.

DENDRITIC CELL. A special type of antigen-presenting cell that is effective in stimulating T cells.

DENGUE. A viral disease transmitted by *Aedes* mosquitoes with symptoms similar to chikungunya.

DENTAL CARIES. Tooth decay caused by microorganisms that convert sugars in food to acids which erode the enamel of a tooth.

DENTAL LASER. A device that generates a low-powered beam of light that is used in place of a dentist's drill to cut away decay from a tooth or remove gum tissue.

DENTIN. The largest part of the tooth, which lies just below enamel and above the pulp.

DEOXYRIBONUCLEIC ACID (DNA). The genetic material in cells that holds the inherited instructions for growth, development, and cellular functioning.

DEPENDENCE. A state in which a person requires a steady concentration of a particular substance to avoid experiencing withdrawal symptoms.

DEPERSONALIZATION. A dissociative symptom in which the patient feels that his or her body is unreal, is changing, or is dissolving.

DEPOT DOSAGE. A form of medication that can be stored in the patient's body tissues for several days or weeks, thus minimizing the risk of the patient forgetting daily doses. Haloperidol and fluphenazine can be given in depot form.

DEPRESSED SKULL FRACTURE. A fracture in which pieces of broken skull press into brain tissue.

DEPRESSION. A mental condition in which people feel extremely sad and lose interest in life. People with depression also may have sleep problems and loss of appetite and may have trouble concentrating and carrying out everyday activities.

DEPRIVATION. A condition of having too little of something.

DEPRIVATIONAL DWARFISM. A condition where emotional disturbances are associated with growth failure and abnormalities of pituitary function.

DEREALIZATION. A dissociative symptom in which the external environment is perceived as unreal or dreamlike.

DERMABRASION. A technique for removing the upper layers of skin with planing wheels powered by compressed air.

DERMATITIS. Inflammation of the skin.

DERMATITIS HERPETIFORMIS. A chronic very itchy skin disease with groups of red lesions that leave spots behind when they heal. It is sometimes associated with cancer of an internal organ.

DERMATOLOGIST. A physician who specializes in diagnosing and treating disorders of the skin.

DERMATOLOGY. The branch of medicine that studies and treats disorders of the skin.

DERMATOME. A surgical instrument used to cut thin slices of skin for grafts.

DERMATOPHYTE. The medical name for three genera of fungi that cause ringworm in humans and domestic pets. The name is derived from two Greek words that mean "skin" and "plant."

DERMATOSIS. A noninflammatory skin disorder.

DERMATOSPARAXIS. Skin fragility caused by abnormal collagen.

DERMIS. A layer of skin sandwiched between the epidermis and the fat under the skin. It contains the blood vessels, nerves, sweat glands, and hair follicles.

DERMOID. A skin-like benign growth that may appear on the ovary and resemble a cyst.

DERVISH. A member of the Sufi order. Their practice of meditation involves whirling ecstatic dance.

DESENSITIZATION. The elimination of an emotional response, such as fear or anxiety, to specific stimuli.

DESFEROXAMINE. The primary drug used in iron chelation therapy. It aids in counteracting the life-threatening buildup of iron in the body associated with long-term blood transfusions.

DESICCATION. Tissue death.

DESIGNER DRUGS. A class of substances that are specifically created to avoid traditional means of detection, including drug laws and testing. Designer drugs often consist of multiple variations of an original compound or they are created to mimic the effects of other popular illicit drugs.

DESMOPRESSIN (DDAVP). A drug used in the treatment of von Willebrand's disease.

DETOXIFICATION. A process of altering the chemical structure of a compound to make it less toxic.

DETRUSOR. Muscle of the bladder wall.

DETRUSOR MUSCLE. Bladder muscle.

DEVELOPMENTAL. Referring to a speech problem or other disorder that arises during a specific stage in human development.

DEVELOPMENTAL DAMAGE. A term that some therapists prefer to personality disorder, on the grounds that it is more respectful of the patient's capacity for growth and change.

DEVIATED SEPTUM. A hole or perforation in the septum, the wall that divides the two nasal cavities.

DEXA BONE DENSITY SCAN. A bone density scan that uses a rotating x-ray beam to measure the strength of an individual's bones and his or her fracture risk.

DIABETES INSIPIDUS. A metabolic disorder in which the pituitary gland produces inadequate amounts of antidiuretic hormone (ADH) or the kidneys are unable to respond adequately to ADH. Primary symptoms are excessive urination and constant thirst.

DIABETES MELLITUS. A disease characterized by an inability to process sugars in the diet due to a decrease in or total absence of insulin production. May require injections of insulin before meals to aid in the metabolism of sugars.

DIABETIC COMA. Reduced level of consciousness that requires immediate medical attention.

DIABETIC HYPERGLYCEMIC HYPEROSMOLAR SYNDROME; HHS. A life-threatening complication of type 2 diabetes in which blood sugar levels are extremely high

WWW.BOOKBAZ.IR

DIABETIC KETOACIDOSIS. A condition caused by low insulin levels where the amount of sugar and ketones in the blood is high.

DIABETIC RETINOPATHY. Retinal disease caused by the damage diabetes does to small blood vessels.

DIAGNOSTIC. The art or act of identifying a disease from its signs and symptoms.

DIAGNOSTIC TESTING. Testing performed to determine if someone is affected with a particular disease.

DIAGNOSTIC WINDOW. A cardiac marker's timeline for rising, peaking, and returning to normal after a heart attack.

DIALECTICAL BEHAVIOR THERAPY (DBT). A type of cognitive-behavioral therapy designed specifically to treat borderline personality disorder.

DIALYSATE. A chemical bath used in dialysis to draw fluids and toxins out of the bloodstream and supply electrolytes and other chemicals to the bloodstream.

DIALYSIS. A blood filtration therapy that replaces the function of the kidneys, filtering fluids and waste products out of the bloodstream. There are two types of dialysis treatment: hemodialysis, which uses an artificial kidney, or dialyzer, as a blood filter; and peritoneal dialysis, which uses the patient's abdominal cavity (peritoneum) as a blood filter.

DIALYSIS PRESCRIPTION. The general parameters of dialysis treatment that vary according to each patient's individual needs. Treatment length, type of dialyzer and dialysate used, and rate of ultrafiltration are all part of the dialysis prescription.

DIALYZER. An artificial kidney, usually composed of hollow fiber, that is used in hemodialysis to eliminate waste products from the blood and remove excess fluids from the bloodstream.

DIAPHRAGM. A sheet of muscle tissue that divides the chest cavity from the abdominal cavity.

DIAPHRAGM BREATHING. Method of deep breathing using the entire lungs.

DIARRHEA. Abnormally frequent bowel movements with fluid stools.

DIASTOLE. Period between contractions of the heart.

DIASTOLIC. The phase of blood circulation in which the heart's pumping chambers (ventricles) are being filled with blood. During this phase, the ventricles are at their most relaxed, and the pressure against the walls of the arteries is at its lowest.

DIASTOLIC BLOOD PRESSURE. The point at which arterial pressure is lowest (when the ventricles are relaxed). The second measurement (usually the lower number) in a blood pressure reading.

DIATHERMY. Also called electrocautery, this is a procedure that heats and destroys abnormal cells.

DIAZEPAM. One of the most commonly used sedative-hypnotic medications.

DIENCEPHALON. A part of the brain that binds the mesencephalon to the cerebral hemispheres. Considered by some as part of the brain stem.

DIENER. In the United States, a morgue technician or attendant who assists a forensic pathologist during an autopsy.

DIETARY REFERENCE INTAKE (DRI). A system of nutritional recommendations used by the Institute of Medicine of the U.S. National Academy of Sciences and the U.S. Department of Agriculture.

DIETARY SUPPLEMENT. A product, such as a vitamin, mineral, herb, amino acid, or enzyme, that is intended to be consumed in addition to an individual's diet with the expectation that it will improve health.

DIETHYLSTILBESTROL (DES). This is a synthetic estrogen drug that is used to treat a number of hormonal conditions. However, it causes problems in developing fetuses and should not be taken during pregnancy. From about 1938 to 1971, DES was given to pregnant women because it was thought to prevent miscarriage. Children of women who took the drug during pregnancy are at risk for certain health problems.

DIETITIAN. A health care professional who specializes in individual or group nutritional planning, public education in nutrition, or research in food science. To be licensed as a registered dietitian (RD) in the United States, a person must complete a bachelor's degree in a nutrition-related field and pass a state licensing examination. Dietitians are sometimes called nutritionists.

DIFFERENTIAL. A blood cell count in which the percentages of cell types are calculated as well as the total number of cells.

DIFFERENTIAL DIAGNOSIS. Comparing and contrasting the signs, symptoms, and laboratory findings of two or more diseases to determine which is causing the patient's condition.

DIFFERENTIATION. The ability to retain one's identity within a family system while maintaining emotional connections with the other members.

DIFFUSE AXONAL INJURY (DAI; ALSO CALLED SHEAR INJURY). Traumatic damage to individual nerve cells resulting in breakdown of overall communication between nerve cells in the brain.

DIFFUSE ESOPHAGEAL SPASM (DES). An uncommon condition characterized by abnormal simultaneous contractions of the esophagus.

DIFFUSION. Passive movement of molecules across a membrane from an area of higher concentration to an area of lower concentration.

DIFFUSION TENSOR IMAGING (DTI). A refinement of magnetic resonance imaging that allows the doctor to measure the flow of water and track the pathways of white matter in the brain. DTI is able to detect abnormalities in the brain that do not show up on standard MRI scans.

DIGEORGE ANOMALY. Also called DeGeorge syndrome (DGS), 22q11.2 deletion syndrome, velocardio-facial syndrome, and others, a syndrome caused by the deletion of a small part of chromosome 22.

DIGESTION. The mechanical, chemical, and enzymatic process in which food is converted into the materials suitable for use by the body.

DIGESTIVE ENZYMES. Molecules that catalyze the breakdown of large molecules (usually food) into smaller molecules.

DIGESTIVE TRACT. The stomach, intestines, and other parts of the body through which food passes.

DIGIT. A finger or a toe.

DIGITAL RECTAL EXAMINATION. A routine screening test that is used to detect any lumps in the prostate gland or any hardening or other abnormality of the prostate tissue. The doctor inserts a gloved and lubricated finger (digit) into the patient's rectum, which lies just behind the prostate. Since a majority of tumors develop in the posterior region of the prostate, they can typically be detected through the rectum.

DIGITALIS. A naturally occurring compound used in the preparation of the medication, digoxin, prescribed to increase the heart rate and strengthen the force of the heart's contractions.

DIHYDROXYACETONE (DHA). A chemical used for staining the skin to simulate a tan.

DILATATION AND CURETTAGE (D & C). A procedure performed under anesthesia during which the cervix is opened more (or dilated) and tissue lining the uterus is scraped out with a metal, spoon-shaped instrument or a suction tube. The procedure can be used to diagnose a problem or to remove growths (polyps).

DILATE. To enlarge, open wide, or distend.

DILATED CARDIOMYOPATHY. Also called congestive cardiomyopathy; cardiomyopathy in which the walls of the heart chambers stretch, enlarging the heart ventricles so they can hold a greater volume of blood than normal.

DILUTE. A solution that has comparatively more fluid in it, relative to the quantity of solute.

DIMERCAPROL (BAL). A chemical agent used to remove excess lead from the body.

DIOPTER (D). A unit of measure for describing refractive power.

DIPHTHERIA. A serious, often fatal, bacterial infection that produces a toxin (poison) and an inflammation in the membrane lining of the throat, nose, trachea, and other tissues.

DIPHTHERIA-TETANUS-PERTUSSIS (DTP). The standard preparation used to immunize children against diphtheria, tetanus, and whooping cough. A so-called "acellular pertussis" vaccine (aP) is usually used since its release in the mid-1990s in a combined vaccine known as DTaP.

DIPHYLLOBOTHRIASIS. Parasitic infection caused by the presence of tapeworms from the *Diphyllobothrium* genus, such as the fish tapeworm (*Diphyllobothrium latum*).

DIPLEGIA. Paralysis affecting like parts on both sides the body, such as both arms or both legs.

DIPLOPIA. The medical term for seeing double.

DIRECT CURRENT (DC). An electric current in which the electric charge moves in only one direction. It is the type of current produced by batteries and solar cells.

DIRECT PRIMARY CARE (DPC). Healthcare delivery in which primary care is offered by the physician directly to the consumer without the involvement of an insurance company. DPC is sometimes used as a synonym for concierge medicine though many writers prefer to distinguish between the two models.

DIRECTION. Bringing about the free balance of the head on the spine and the resulting release of the

WWW.BOOKBAZ.IR

erector muscles of the back and legs which establish improved coordination.

DISACCHARIDE. Any sugar formed when two monosaccharides are joined together and a molecule of water is removed.

DISCHARGE PLANNER. A healthcare professional who helps patients arrange for health and home care needs after they go home from the hospital.

DISEASE-MODIFYING ANTIRHEUMATIC DRUG (DMARD). A class of antirheumatic drugs, including chloroquine, methotrexate, cyclosporine, and gold compounds, that influence the disease process itself and do not only treat its symptoms.

DISENFRANCHISED GRIEF. Grief that cannot be openly expressed because the death or other loss cannot be publicly acknowledged.

DISEQUILIBRIUM. Difficulty with equilibrium that can mean a deficiency in balance and/or orientation.

DISFLUENCY. Any difficulty in fluent speech, including stuttering.

DISINFECTED. Decreased the number of microorganisms on or in an object.

DISK. A ringlike structure that fits between the vertebrae in the spine to protect the bones, nerves, and blood vessels. The outer layer is a tough, fibrous tissue, and the inner core is composed of more elastic tissue.

DISKECTOMY. The surgical removal of a portion or all of an intervertebral disk.

DISLOCATION. Displacement of bones at a joint.

DISORDER OF SEX DEVELOPMENT (DSD). The term that is increasingly preferred for an atypical pattern of chromosomal, genital, or gonadal development. It is also known as disorder of sex differentiation.

DISPARITY. Inequality or lack of similarity; may be associated with differences in care or treatment.

DISPERSANT. Chemicals that break up spilled oil into small particles that can be further scattered and broken down by water and wind, thus sparing oil damage to marine and coastal environments.

DISSECTION. A process of biological examination in which an organism or part of one is taken apart in order to determine its internal structure in detail.

DISSEMINATED. Spread to other tissues.

DISSEMINATED INTRAVASCULAR COAGULATION (DIC). A serious medical condition that develops when the normal balance between bleeding and clotting is disturbed. Excessive bleeding and clotting injures body organs, and causes anemia or death.

DISSOCIATION. A reaction to trauma in which the mind splits off certain aspects of the traumatic event from conscious awareness. It can affect the patient's memory, sense of reality, and sense of identity.

DISSOCIATIVE. Disconnection from oneself.

DISSOCIATIVE AMNESIA. A dissociative disorder characterized by loss of memory for a period or periods of time, which may occur as a result of a traumatic event.

DISSOCIATIVE DISORDERS. A group of mental disorders in which dissociation is a prominent symptom. Patients with dissociative disorders have a high rate of self-mutilation.

DISSOCIATIVE IDENTITY DISORDER (DID). Term that replaced Multiple Personality Disorder (MPD). A condition in which two or more distinctive identities or personality states alternate in controlling a person's consciousness and behavior.

DISTAL. Away from the point of origin.

DISTAL MUSCULAR DYSTROPHY (DD). A form of muscular dystrophy that usually begins in middle age or later, causing weakness in the muscles of the feet and hands.

DISTAL PHALANX. The outermost bone of any finger or toe.

DISTAL TUBULE. The portion of the kidney tubule that lies furthest away from the point where fluid from the blood enters the tubule.

DISTANT SITE. The site where the telehealth physician or other health care provider is located. It is also known as the "hub site."

DISULFIRAM. A medication that has been used since the late 1940s as part of a treatment plan for alcohol abuse. Disulfiram, which is sold under the trade name Antabuse, produces changes in the body's metabolism of alcohol that cause headaches, vomiting, and other unpleasant symptoms if the patient drinks even small amounts of alcohol.

DIURETIC. A substance that removes water from the body by increasing urine production.

DIVERTICULA. A diverticulum of the colon is a sac or pouch in the colon wall that is usually asymptomatic (without symptoms), but may cause difficulty if it becomes inflamed. Diverticula is the plural of diverticulum.

DIVERTICULITIS. A condition of the diverticulum of the intestinal tract, especially in the colon, where inflammation may cause distended sacs extending from the colon and pain.

DIVERTICULUM. Pouches that project off the wall of the intestine.

DNA ANALYTICS. The use of fragments of DNA to identify and/or classify the organism from which the sample came.

DNA PROBE. An agent that binds directly to a predefined sequence of nucleic acids.

DNA TESTING. Analysis of DNA (the genetic component of cells) in order to determine changes in genes that may indicate a specific disorder.

DO NOT RESUSCITATE ORDER. A directive specifying that if an individual's heart stops, he or she should not receive cardiopulmonary resuscitation (CPR).

DOCOSAHEXAENOIC ACID (DHA). A long-chain omega-3 fatty acid found primarily in oily fish. It is important for the development of the brain and the retina of the eye.

DOMINANT TRAIT. A genetic trait where one copy of the gene is sufficient to yield an outward display of the trait; dominant genes mask the presence of recessive genes; dominant traits can be inherited from only one parent.

DONEPEZIL HYDROCHLORIDE (ARICEPT). A drug that increases the levels of acetylcholine in the brain.

DONOR. A person who supplies organ(s), tissue, or blood to another person for transplantation.

DONOVAN BODIES. Rod-shaped oval organisms found in tissue samples from patients with granuloma inguinale. Donovan bodies appear deep purple when stained with Wright's stain.

DOPA. The common name for a natural chemical (3, 4-dihydroxyphenylalanine) made by the body during the process of making melanin.

DOPAMINE. A chemical in brain tissue that serves to transmit nerve impulses and helps to regulate movement and emotions.

DOPAMINE RECEPTOR ANTAGONISTS (DAS). The older class of antipsychotic medications, also called neuroleptics. These primarily block the site on nerve cells that normally receive the brain chemical dopamine.

DOPPLER. The Doppler effect refers to the apparent change in frequency of sound wave echoes returning to a stationary source from a moving target. If the object is moving toward the source, the frequency increases; if the object is moving away, the frequency decreases. The size of this frequency shift can be used to compute the object's speed—be it a car on the road or blood in an artery. The Doppler effect holds true for all types of radiation, not just sound.

DOPPLER SCANNING. A procedure in which ultrasound images are used to watch a moving structure such as the flow of blood or the beating of the heart.

DOPPLER ULTRASONOGRAPHY. A diagnostic ultrasound procedure that uses reflected sound waves to evaluate blood flow through major arteries and veins.

DOPPLER ULTRASOUND. A diagnostic procedure that uses sound waves to evaluate blood flow through major arteries and veins.

DORSAL. Referring to a position closer to the back than to the stomach. The laminae in the spinal column are located on the dorsal side of each vertebra.

DORSAL RHIZOTOMY. A surgical procedure that cuts nerve roots to reduce spasticity in affected muscles.

DORSAL ROOT ENTRY ZONE (DREZ). A type of nerve surgery for postherpetic neuralgia that is occasionally used when the patient can get no other pain relief. The surgery destroys the area where damaged nerves join the central nervous system, thereby interfering with inappropriate pain messages from nerves to the brain.

DOSHA. One of three constitutional types, either vata, pitta, or kapha, found in Ayurvedic medicine.

DOWN SYNDROME. A chromosomal disorder caused by an extra copy or a rearrangement of chromosome 21. Children with Down syndrome have varying degrees of intellectual disability (ID) and may have heart defects.

DRESSING. The covering of a wound.

DRUG INTERACTION. A chemical or physiological reaction that can occur when two different drugs are taken together.

DRUSEN. Clumps of pigment that accumulate under the retina when wastes build up faster than they can be removed. Drusen are a sign of dry age-related macular degeneration.

DRY EYE. Corneal dryness due to insufficient tear production.

WWW.BOOKBAZ.IR

DRY SOCKET. A painful condition following tooth extraction in which a blood clot does not properly fill the empty socket. Dry socket leaves the underlying bone exposed to air and food particles.

DTAP. A routine childhood immunization with the full-strength diphtheria (D), tetanus toxoid (T), and acellular pertussis (aP) combination vaccine.

DUAL ELIGIBLES. Low-income elderly and those with physical or mental disabilities who are eligible for both Medicaid and Medicare.

DUAL-ENERGY X-RAY ABSORPTIOMETRY (DXA). A direct method of calculating body fat that involves scanning the patient with two x-ray beams of different energy levels. DXA is used primarily to measure bone mineral density, however, rather than percentage of body fat.

DUBOWITZ EXAM. A standardized test that scores responses to 33 specific neurological stimuli to estimate an infant's neural development and gestational age.

DUCHENNE MUSCULAR DYSTROPHY (DMD). The most severe form of muscular dystrophy, DMD usually affects young boys and causes progressive muscle weakness, usually beginning in the legs.

DUCT. A tube through which various substances can pass. These substances can travel through ducts to another organ or into the bloodstream.

DUCTAL ADENOCARCINOMA. A malignant tumor arising from the duct cells within a gland.

DUCTAL CARCINOMA. Breast cancer that originates in the lining of the milk duct; ductal carcinoma in situ (DCIS) is ductal cancer that has not become invasive.

DUCTUS. The blood vessel that joins the pulmonary artery and the aorta. When the ductus does not close at birth, it causes a type of congenital heart disease called patent ductus arteriosus.

DUCTUS ARTERIOSUS. A blood vessel in the human fetus that connects the aortic arch to the pulmonary artery before birth and normally closes shortly after birth in healthy newborns.

DUODENAL. Refers to the duodenum, or the first part of the small intestine.

DUODENAL ATRESIA. Closure or blockage of the duodenum, the upper section of the small intestine.

DUODENUM. The first of the three segments of the small intestine. The duodenum connects the stomach and the jejunum.

DUPUYTREN'S CONTRACTURE. Shortening and thickening of connective tissue in the palm causing the fingers to pull in.

DURA. A tough fibrous membrane that covers and protects the spinal cord.

DURA MATER. One of the membranes that sheathes the spinal cord and brain; the outermost layer.

DWARFISM. A congenital disease of bone growth that results in short stature and weak bones.

DWARFISM, PITUITARY. Short stature. When caused by inadequate amounts of growth hormone (as opposed to late growth spurt or genetics), hGH deficiency results in abnormally slow growth and short stature with normal proportions.

DYANA. Yoga meditation.

DYSBIOSIS. The condition that results when the natural flora of the gut are thrown out of balance, such as when antibiotics are taken.

DYSENTERY. Intestinal infection marked by diarrhea containing blood and mucus.

DYSKINESIA. Impaired ability to make voluntary movements.

DYSLEXIA. An inability to read, write, or spell words in spite of the ability to see and recognize letters. Dyslexia is an autosomal dominant disorder that occurs more frequently in males.

DYSMENORRHEA. Painful menstruation.

DYSPAREUNIA. Difficult or painful sexual intercourse.

DYSPEPSIA. A vague feeling of being too full and having heartburn, bloating, and nausea. Usually felt after eating.

DYSPHAGIA. Difficulty or discomfort in swallowing.

DYSPHORIA. Feelings of anxiety, restlessness, and dissatisfaction.

DYSPLASIA. Abnormal cellular changes that may become cancerous.

DYSPLASTIC NEVUS SYNDROME. A familial syndrome characterized by the presence of multiple atypical appearing moles, often at a young age.

DYSPNEA. Difficulty in breathing. Usually associated with heart or lung diseases.

DYSSOMNIA. A primary sleep disorder in which the patient suffers from changes in the quantity, quality, or timing of sleep.

DYSTHYMIA. Type of affective disorder or mood disorder that often resembles a less severe, yet more chronic form of major.

DYSTOCIA. Failure to progress in labor, either because the cervix will not dilate (expand) further or (after full dilation) the baby's head does not descend through the mother's pelvis.

DYSTONIA. Painful involuntary muscle cramps or spasms.

DYSTROPHIN. A protein that helps muscle tissue repair itself. Both Duchenne muscular dystrophy and Becker muscular dystrophy are caused by flaws in the gene that instructs the body how to make this protein.

DYSURIA. Painful or difficult urination.

DYSVASCULAR AMPUTATION. Amputation due to vascular disease.

E

EAR CANDLING. An alternative method for removing impacted cerumen with a lighted hollow cone of paraffin or beeswax. It does not work, and is not considered an acceptable treatment for any ear problem or disorder.

EAR SPECULUM. A cone- or funnel-shaped attachment for an otoscope which is inserted into the ear canal to examine the eardrum.

EARDRUM. A paper-thin covering stretching across the ear canal that separates the middle and outer ears.

EATING DISORDER. A condition characterized by an abnormal attitude towards food, altered appetite control, and unhealthy eating habits that affect health and the ability to function normally.

EBOLA. A severe—often fatal—viral disease that can be transmitted to humans from other mammals and spreads rapidly through communities; the cause of a major 2014 epidemic in West Africa.

ECCHYMOSIS (PLURAL, ECCHYMOSES). The medical term for a bruise. Ecchymoses may develop around the eyes following a nasal fracture.

ECHOCARDIOGRAM. A procedure in which high frequency sound waves harmlessly bounce off organs in the body providing an image so one can determine their structure and function.

ECHOCARDIOGRAPH. A procedure in which high frequency sound waves harmlessly bounce off organs in the body providing an image so one can determine their structure and function.

ECHOCARDIOGRAPHY. A diagnostic test using reflected sound waves to study the structure and motion of the heart muscle.

ECHOLALIA. Involuntary echoing of the last word, phrase, or sentence spoken by someone else or sound in the environment.

ECHOPRAXIA. The imitation of the movement of another individual.

ECTOPARASITE. Any parasite that lives on the surface of its host. Fleas are ectoparasites.

ECTOPIA LENTIS. Dislocation of the lens of the eye. It is one of the most important single indicators in diagnosing Marfan syndrome.

ECTOPIC. In an abnormal position.

ECTOPIC BEAT. Abnormal heartbeat arising elsewhere than from the sinoatrial node.

ECTOPIC PARATHYROID TISSUE. Parathyroid tissue located in an abnormal place.

ECTOPIC PREGNANCY. A pregnancy in which the fertilized egg has implanted outside the uterus, most often in the Fallopian tubes, although in some cases the pregnancy implants in the ovary or in the abdomen. A ruptured ectopic pregnancy is a medical emergency.

ECZEMA. Atopic dermatitis; a skin condition resulting from exposure to airborne, food, or drug allergens.

EDEMA. Swelling caused by fluid buildup in tissues.

EDETATE CALCIUM DISODIUM (EDTA CALCIUM). A chemical agent used to remove excess lead from the body.

EDTA. A colorless compound used to keep blood samples from clotting before tests are run. Its chemical name is ethylenediaminetetraacetic acid.

EFFACEMENT. The thinning out of the cervix that normally occurs along with dilation shortly before delivery.

EFFERENT. Refers to peripheral nerves that carry signals away from the brain and spinal cord. These nerves carry out motor and autonomic functions.

EFFERENT NERVES. Nerves that convey impulses away from the central nervous system to the periphery.

WWW.BOOKBAZ.IR

EFFUSION. A collection of fluid which has leaked out into some body cavity or tissue.

EGO-SYNTONIC. Consistent with one's sense of self, as opposed to ego-alien or dystonic (foreign to one's sense of self). Ego-syntonic traits typify patients with personality disorders.

EHLERS-DANLOS SYNDROME. A rare inheritable disease of the connective tissue marked by very elastic skin, very loose joints, and very fragile body tissue.

E-HOOKAH. An informal term for a personal vaporizer that does not use a fluid containing nicotine. E-hookahs are also called hookah pens or vape pens.

EIGHTH CRANIAL NERVE DISEASE. A disorder affecting the eighth cranial nerve, characterized by a loss of hearing and/or balance.

EJACULATION. The process by which semen is ejected by the erect penis.

EJACULATORY INCOMPETENCE. The inability to ejaculate within the vagina.

EJECTION FRACTION. A measure of the portion of blood that is pumped out of a filled ventricle.

ELASTIC FIBER. Fibrous, stretchable connective tissue made primarily from proteins, elastin, collagen, and fibrillin.

ELECTIVE SURGERY. Surgery that is chosen by the patient (or a guardian); an elective operation may be beneficial to the patient but is not urgently needed.

ELECTOLYTES. Salts, such as sodium and chloride.

ELECTRO-ACUPUNCTURE. Percutaneous electrical nerve stimulation (PENS); acupuncture in which a weak electrical current is passed through acupuncture needles inserted in the skin.

ELECTROCARDIOGRAM (ECG OR EKG). A test used to measure electrical impulses coming from the heart in order to gain information about its structure or function.

ELECTROCAUTERY. The use of a low-voltage electrified probe used to remove tissue through cauterization (burning).

ELECTROCOAGULATION. The coagulation or destruction of tissue through the application of a high-frequency electrical current.

ELECTROCONVULSIVE THERAPY. This type of therapy is used to treat major depression and severe mental illness that does not respond to medications. A measured dose of electricity is introduced into the brain in order to produce a convulsion. Electroconvulsive therapy is safe and effective.

ELECTRODE. Tiny wires in adhesive pads that are applied to the body for EKG measurement.

ELECTRODESICCATION. The process of making dry, dull, or lifeless with the use of electrical current.

ELECTROENCEPHALOGRAM (EEG). A chart of the brain waves picked up by the electrodes placed on the scalp. Changes in brain wave activity can be an indication of nervous system disorders.

ELECTROLYTE. Ions in the body that participate in metabolic reactions. The major human electrolytes are sodium ($Na+$), potassium ($K+$), calcium ($Ca\ 2+$), magnesium ($Mg2+$), chloride ($Cl–$), phosphate ($HPO_4\ 2–$), bicarbonate ($HCO_3–$), and sulfate ($SO_4\ 2–$).

ELECTROMYOGRAPHIC BIOFEEDBACK. A method for relieving jaw tightness by monitoring the patient's attempts to relax the muscle while the patient watches a gauge. The patient gradually learns to control the degree of muscle relaxation.

ELECTROMYOGRAPHY (EMG). A test that uses electrodes to record the electrical activity of muscle. The information gathered is used to find disorders of the nerves that serve the muscles.

ELECTRON. One of the small particles that make up an atom. An electron has the same mass and amount of charge as a positron, but the electron has a negative charge.

ELECTRONIC FETAL NONSTRESS TEST. A test in which electronic monitors attached to the mother's abdomen to detect contractions of the uterus as well as the baby's heartbeat and movements.

ELECTRONYSTAGMOGRAPHY. A method for measuring the electricity generated by eye movements. Electrodes are placed on the skin around the eye and the individual is subjected to a variety of stimuli so that the quality of eye movements can be assessed.

ELECTROPHORESIS. A technique for separating various blood fractions by running an electric current through a gel containing a blood sample.

ELECTROPHYSIOLOGICAL STUDY. A test that monitors the electrical activity of the heart in order to diagnose arrhythmia. An electrophysiological study measures electrical signals through a cardiac catheter that is inserted into an artery in the leg and guided up into the atrium and ventricle of the heart.

ELECTROPHYSIOLOGY. Study of how electrical signals in the body relate to physiologic function.

ELECTROSURGICAL DEVICE. A medical device that uses electrical current to cauterize or coagulate tissue during surgical procedures, often used in conjunction with laparoscopy, colonoscopy, or sigmoidoscopy.

ELECTROTHERAPY. The treatment of body tissues by passing electrical currents through them, stimulating the nerves and muscles.

ELEMENTAL MERCURY. Metallic mercury; quicksilver; a heavy, silvery, poisonous metallic element that is a liquid at room temperature but vaporizes readily.

ELEPHANTIASIS. A condition characterized by the gross enlargement of limbs and/or the genitalia that is also accompanied by a hardening and stretching of the overlying skin.

ELIMINATION DIET. A diet in which the patient excludes a specific food (or group of foods) for a period of time in order to determine whether the food is responsible for symptoms of an allergy or other disorder. Elimination diets are also known as food challenge diets.

E-LIQUID. The solution contained in an e-cigarette that is vaporized when the device is used. Also called juice, it typically contains propylene glycol, vegetable glycerine, flavorings of various types, and (in most cases) nicotine.

ELIXIR. Liquid that contains alcohol, water, and a therapeutic agent.

EMBOLIC STROKE. Cerebral embolism; a type of ischemic stroke in which a blood clot moves through the circulatory system to block an artery in the brain or neck.

EMBOLISM. A blood clot, air bubble, or clot of foreign material that travels and blocks the flow of blood in an artery. When blood supply to a tissue or organ is blocked by an embolism, infarction (death of the tissue the artery feeds) occurs. Without immediate and appropriate treatment, an embolism can be fatal.

EMBOLIZATION. A technique to stop or prevent hemorrhage by introducing a foreign mass, such as an air-filled membrane (balloon), into a blood vessel to block the flow of blood.

EMBOLUS. An embolus is something that blocks the blood flow in a blood vessel. It may be a gas bubble, a blood clot, a fat globule, a mass of bacteria, or other foreign body. It usually forms somewhere else and travels through the circulatory system until it gets stuck.

EMBRYO. The very beginning stages of development of an organism.

EMBRYONIC. The very beginning stages of development of an organism.

EMERGENCY CONTRACEPTIVE PILLS (ECPS). Medication containing synthetic hormones for preventing pregnancy after unprotected vaginal intercourse.

EMERGENT DISEASE. An infectious disease that appears in a population for the first time, rapidly increases in incidence or geographic range, becomes more virulent or treatment-resistant, or re-emerges after a long period of control or presumed elimination.

EMERGING INFECTIOUS DISEASE (EID). An infectious disease whose incidence has increased within the last 35 years and may increase further in the near future.

EMESIS. The medical term for vomiting.

EMESIS BASIN. A basin used to collect sputum or vomit.

EMETIC. A medication or substance given to induce vomiting.

EMLA. Eutectic mixture of local anesthetics, a drug combination for use on intact skin.

EMMENAGOGUE. A medication or herbal preparation given to bring on a woman's menstrual period.

EMOLLIENT. A paste or compound having a soothing effect when applied to the skin.

EMPHYSEMA. A chronic obstructive pulmonary disease in which the destruction of air sac walls form abnormally large air sacs that have reduced gas exchange ability and tend to retain air within the lungs. Symptoms include labored breathing, the inability to forcefully blow air out of the lungs, and an increased susceptibility to respiratory tract infections.

EMPIRIC THERAPY. Treatment (usually with medications) that is started before the diagnosis of the patient's disease is confirmed.

EMPYEMA. The collection of pus in a body cavity, particularly the lung or pleural cavity.

ENAMEL. The hard outer surface of a tooth.

ENCEPHALITIS. An inflammation or infection of the brain and spinal cord caused by a virus or as a complication of another infection.

ENCEPHALOCELES. Protrusion of the brain through a defect in the skull.

WWW.BOOKBAZ.IR

ENCEPHALOPATHY. Brain disease, damage, or malfunction; usually caused by an infection, liver damage, anoxia, or kidney failure.

ENCOPRESIS. Abnormalities relating to bowel movements that can occur as a result of stress or fear.

ENCYSTED. Enclosed in a cyst or capsule. Flukes spend part of their life cycle as encysted larvae.

ENDARTERECTOMY. A surgical procedure in which diseased tissue and atherosclerotic plaque are removed from the inside of an artery.

ENDARTERITIS. Chronic inflammation of the inner layer of arteries.

ENDEMIC. Restricted or peculiar to a specific locale or region; especially a disease that is prevalent only in particular populations.

ENDEMIC AREA. A geographical area where a particular disease is prevalent.

ENDEMIC DISEASE. An infectious disease that occurs frequently in a specific geographical locale. The disease often occurs in cycles. Influenza is an example of an endemic disease.

ENDOCARDITIS. Inflammation of the endocardium, the inner layer of heart tissue.

ENDOCARDIUM. The inner wall of the heart muscle, which also covers the heart valves.

ENDOCERVICAL CURETTAGE. Biopsy performed with a curette to scrape the mucous membrane of the cervical canal.

ENDOCRINE GLAND. A ductless gland, such as the pituitary, thyroid, or adrenal gland, that secretes its products directly into the blood or lymph.

ENDOCRINE SYSTEM. A system of ductless glands that secrete hormones that regulate a variety of body processes, including growth and sexual maturation. A doctor who specializes in diseases and disorders of these glands is called an endocrinologist.

ENDOCRINOLOGIST. A doctor who specializes in diagnosing and treating disorders of the endocrine glands and the hormones they secrete.

ENDODONTIC. Pertaining to the inside structures of the tooth, including the dental pulp and tooth root, and the periapical tissue surrounding the root.

ENDODONTIST. A dentist who specializes in the diagnosis and treatment of disorders affecting the inside structures of teeth.

ENDOMETRIAL BIOPSY. The removal of tissue either by suction or scraping of samples of tissue from the uterus. The cervix is not dilated. The procedure has a lower rate of diagnostic accuracy than a D & C, but can be done as an office procedure under local anesthesia.

ENDOMETRIAL CANCER. Cancer of the inner mucous membrane of the uterus.

ENDOMETRIAL HYPERPLASIA. A condition in which the endometrium produces an overgrowth of cells during the menstrual cycle. It is not cancerous in itself but is a risk factor for endometrial cancer.

ENDOMETRIAL IMPLANTS. Growths of endometrial tissue that attach to organs, primarily in the pelvic cavity.

ENDOMETRIAL POLYPS. Growths in the lining of the uterus (endometrium) that may cause bleeding and can develop into cancer.

ENDOMETRIOMA. A type of cyst formed when endometrial tissue grows within the ovary.

ENDOMETRIOSIS. A condition in which the tissue that normally lines the uterus (endometrium) grows in other areas of the body, causing pain, irregular bleeding, and frequently infertility.

ENDOMETRITIS. Inflammation of the endometrium or mucous membrane of the uterus.

ENDOMETRIUM. The tissue lining the uterus that grows and sheds each month during a woman's menstrual cycle.

ENDOMYOCARDIAL BIOPSY. Removal of a small sample of heart tissue to check for signs of damage caused by organ rejection.

ENDOPHTHALMITIS. Inflammation of the eyeball.

ENDORPHINS. A group of proteins with powerful pain-killing properties that originate naturally in the brain.

ENDOSCOPE. A narrow, flexible tube with a fiberoptic light on it, used to pass into the body for a variety of medical examinations.

ENDOSCOPE, ENDOSCOPY. An endoscope as used in the field of gastroenterology is a thin flexible tube which uses a lens or miniature camera to view various areas of the gastrointestinal tract. When the procedure is performed to examine certain organs such as the bile ducts or pancreas, the organs are not viewed directly, but rather indirectly through the injection of x-ray dye. The performance of an exam using an endoscope

is referred by the general term endoscopy. Diagnosis through biopsies or other means and therapeutic procedures can be done with these instruments.

ENDOSCOPIC. Of, relating to, or performed by means of an endoscope or endoscopy.

ENDOSCOPIC RETROGRADE CHOLANGIOPANCREATOGRAPHY (ERCP). A diagnostic procedure for mapping the pancreatic and common bile ducts. A flexible tube with a light transmitter (fiberoptics) is placed in the duct. A contrast dye is instilled directly into the duct and a series of x-ray images are taken.

ENDOSCOPIC ULTRASONOGRAPHY (EUS). Diagnostic imaging technique where an ultrasound probe is inserted down a patient's throat to determine if a tumor is present.

ENDOSCOPIC ULTRASOUND (EUS). A medical procedure in which sound waves are sent to the stomach wall by an ultrasound probe attached to the end of an endoscope. The pattern of echoes generated by the reflected sound waves are translated into an image of the stomach wall by a computer.

ENDOSCOPY. The examination of the inside of an organ with an instrument that has a light at the end of it and an optical system for examination of the organ.

ENDOSTEAL IMPLANTS. Dental implants that are placed within the bone.

ENDOTHELIAL. A layer of cells that lines the inside of certain body cavities, for example, blood vessels.

ENDOTRACHEAL. Placed within the trachea.

ENDOTRACHEAL TUBE. A hollow tube that is inserted into the windpipe to administer anesthesia.

ENDOVASCULAR GRAFTING. A procedure that involves the insertion of a delivery catheter through a groin artery into the abdominal aorta under fluoroscopic guidance.

END-STAGE HEART FAILURE. Severe heart disease that does not respond adequately to medical or surgical treatment.

END-STAGE LUNG DISEASE. The final stages of lung disease, when the lung can no longer keep the blood supplied with oxygen. End-stage lungs in pulmonary fibrosis have large air spaces separated by bands of inflammation and scarring.

END-STAGE RENAL DISEASE (ESRD). Total kidney failure; chronic kidney failure is diagnosed as ESRD when kidney function falls to 5-10% of capacity.

ENEMA. A liquid that is injected through the anus and into the lower intestine to stimulate defecation.

ENGRAFTMENT. The process of transplanted stem cells reproducing new cells.

ENHANCEMENT. A secondary refractive procedure performed in an attempt to achieve better visual acuity.

ENKEPHALINES. Peptide produced by the body that have analgesic properties.

ENOPHTHALMOS. A condition in which the eye falls back into the socket and inhibits proper eyelid function.

ENRICHED. Having some of the nutrients that were lost during processing added back.

ENTERAL NUTRITION. Nourishment given through a tube or stoma directly into the small intestine, thus bypassing the upper digestive tract.

ENTERIC. Pertaining to the intestine.

ENTERIC FEVER. A term that is sometimes used for either typhoid or paratyphoid fever.

ENTEROCELE. Bulging of the intestine into the upper part of the vagina.

ENTEROSTOMAL THERAPIST (ET). A specialized counselor, usually a registered nurse, who provides ostomy patients with education and counseling before the operation. After surgery, the ET helps the patient learn to take care of the stoma and appliance, and offers long-term emotional support.

ENTEROTOXIGENIC. Refers to an organism that produces toxins in the gastrointestinal tract that cause such things as vomiting, diarrhea, and other symptoms of food poisoning.

ENTEROTOXIN. A type of harmful protein released by bacteria and other disease agents that affects the tissues lining the intestines.

ENTEROVIRUS. Any of a group of viruses that primarily affect the gastrointestinal tract.

ENTRAINMENT. The patterning of body processes and movements to the rhythm of music.

ENUCLEATION. Surgical removal of the eye.

ENVENOMATION. Exposure to venom by bites or stings from insects, reptiles, and fish.

ENVIRONMENTAL EPIDEMIOLOGY. The study of the effects of exposure to environmental hazards on human health.

WWW.BOOKBAZ.IR

ENZYMATIC REPLACEMENT THERAPY. A treatment method used to replace missing enzymes. It is possible to synthesize enzymes and then inject them intravenously into patients.

ENZYME. A type of protein, produced in the body, that brings about or speeds up chemical reactions.

ENZYME ACTIVITY. A measure of the ability of an enzyme to catalyze a specific reaction.

ENZYME-LINKED IMMUNOSORBENT ASSAY (ELISA). An immunological test for detecting specific substances, including viruses and antibodies.

EOSINOPHIL. Segmented white blood cell with large orange-red granules that increases in response to parasitic infections and allergic reactions.

EOSINOPHILIA. An abnormal increase in the number of a specific type of white blood cell. Eosinophilia is a characteristic of all types of roundworm infections.

EPICONDYLE. A projection on the surface of a bone; often an area for muscle and tendon attachment.

EPICONDYLITIS. A painful and sometimes disabling inflammation of the muscle and surrounding tissues of the elbow caused by repeated stress and strain on the forearm near the lateral epicondyle of the humerus (arm bone).

EPIDEMIC. Affecting many individuals in a community or population and spreading rapidly.

EPIDEMIC PAROTITIS. The medical name for mumps.

EPIDEMIOLOGY. The study of disease occurrence in human populations.

EPIDERMAL. Referring to the thin outermost layer of the skin, itself made up of several layers, that covers and protects the underlying dermis (skin).

EPIDERMAL GROWTH FACTOR RECEPTOR (EGFR). EGFR1 (HER1); a cell-surface protein that initiates growth and proliferation and is a marker for certain cancers.

EPIDERMIS. The thin layer of skin cells at the surface of the skin.

EPIDERMOLYTIC. Damaging to the top layer of skin.

EPIDIDYMIS. The duct between the testis and the vas deferens for the passage of sperm.

EPIDIDYMITIS. Inflammation of the small tube that rests on top of the testicle and is part of the system that carries sperm from the testicle to the penis. The condition can be successfully treated with antibiotics, if necessary.

EPIDIDYMO-ORCHITIS. Inflammation of both the testes and a part of the spermatic duct system.

EPIDURAL ANESTHESIA. A type of anesthesia that is injected into the epidural space of the spinal cord to numb the nerves leading to the lower half of the body.

EPIDURAL HEMATOMA. Bleeding into the area between the skull and the dura, the tough, outermost brain covering.

EPIDURAL SPACE. The space surrounding the spinal fluid sac.

EPIGLOTTIS. A leaf-like piece of cartilage extending upwards from the larynx, which can close like a lid over the trachea to prevent the airway from receiving any food or liquid being swallowed.

EPIGLOTTITIS. A leaf-like piece of cartilage extending upwards from the larynx, which can close like a lid over the trachea to prevent the airway from receiving any food or liquid being swallowed.

EPIKERATOPHAKIA. A procedure in which the donor cornea is attached directly onto the host cornea.

EPI-LASIK. A surgical procedure that uses a blunt, plastic oscillating blade called an epithelial separator to cut a flap in the cornea.

EPILEPSY. A brain disorder with symptoms that include seizures.

EPILEPTOLOGIST. A physician who specializes in the treatment of epilepsy.

EPINEPHRINE. Also called adrenaline; it is a naturally occurring hormone released by the adrenal glands in response to signals from the sympathetic nervous system. These signals are triggered by stress, exercise, or by emotions such as fear.

EPISIOTOMY. Incision of the perineum, the area between the vulva and the anus, to assist delivery and avoid severe tearing of the perineum.

EPISTAXIS. The medical term for a nosebleed.

EPITHELIAL. Of or relating to the epithelium, the layer of cells forming the epidermis of the skin and the surface layer of mucous membranes.

EPITHELIAL CELLS. Cells that form a thin surface coating on the outside of a body structure.

EPITHELIUM. Cells composing the lining of an organ.

EPITOPE. A portion of a protein or other molecule that is the specific target of an immune response.

EPSTEIN-BARR VIRUS (EBV). A virus in the herpes family that causes mononucleosis.

EQUATOR. Imaginary line encircling the eyeball and dividing the eye into a front and back half.

ERADICATE. To completely do away with something, eliminate it, end its existence.

ERBIUM:YAG. A crystal made of erbium, yttrium, aluminum, and garnet that produces light that is well absorbed by the skin, so it is used for skin resurfacing treatments.

ERECTILE DYSFUNCTION (ED). The inability to get or maintain an erection.

ERGONOMICS. The study of the relationship between people and their working environment.

ERGOTAMINE. A drug used to prevent or treat migraine headaches. This can cause vomiting, diarrhea, and convulsions in infants.

ERUPTION. The process of a tooth breaking through the gum tissue to grow into place in the mouth.

ERYTHEMA. The medical term for redness of the skin produced by congestion of the capillaries in the skin.

ERYTHEMA MIGRANS (EM). A red skin rash that is one of the first signs of Lyme disease in the majority of patients.

ERYTHEMA MULTIFORME. A type of hypersensitivity (allergic) reaction that occurs in response to medications, infections, or illness. Medications associated with erythema multiforme include sulfonamides, penicillins, barbiturates, and phenytoin. Associated infections include herpes simplex and mycoplasma infections. In severe cases, the condition is called Stevens-Johnson syndrome.

ERYTHROBLASTOPENIA. A deficiency in the cells that create red blood cells. This condition may be severe and life-threatening, but there is a transient form, seen in young children, which resolves spontaneously and does not recur.

ERYTHROBLASTOSIS FETALIS. A disorder of newborn infants marked by a high level of immature red blood cells (erythroblasts).

ERYTHROCYTE. The name for red blood cells or red blood corpuscles. These components of the blood are responsible for carrying oxygen to tissues and removing carbon dioxide from tissues.

ERYTHROCYTE SEDIMENTATION RATE (ESR). The speed at which red blood cells sink in a tube of freshly drawn blood, which is a rough measure of clotting disorders or inflammation.

ERYTHROCYTES. Red blood cells.

ERYTHRODERMA. An abnormal reddening of the entire skin surface.

ERYTHROGENIC TOXIN. A toxin or agent produced by the scarlet fever-causing bacteria that causes the skin to turn red.

ERYTHROMYCIN. An antibiotic that can be used instead of penicillin.

ERYTHROPLAKIA. A flat red patch or lesion in the mouth.

ERYTHROPOIESIS. The process through which new red blood cells are created; it begins in the bone marrow.

ERYTHROPOIETIC. Referring to the creation of new red blood cells.

ERYTHROPOIETIN. A hormone that stimulates production of red blood cells.

ESCHAR. A crusty, blackish scab.

ESCHERICHIA COLI. A type of enterobacterium responsible for most cases of severe bacterial diarrhea in the United States.

ESCITALOPRAM OXALATE. An SSRI that is very similar to citalopram hydrobromide.

ESOPHAGEAL ATRESIA. Blockage or closure of the esophagus, the tube leading from the mouth to the stomach.

ESOPHAGEAL MANOMETRY. A test in which a thin tube is passed into the esophagus to measure the degree of pressure exerted by the muscles of the esophageal wall.

ESOPHAGEAL SPHINCTER. A circular band of muscle that closes the last few centimeters of the esophagus and prevents the backward flow of stomach contents.

ESOPHAGEAL VARIX. An enlarged vein of the esophagus. (Plural: esophageal varices.)

ESOPHAGITIS. Inflammation of the esophagus.

ESOPHAGOGASTRODUODENOSCOPY (EGD). A test that involves visually examining the lining of the esophagus, stomach, and upper duodenum with a flexible fiber-optic endoscope.

WWW.BOOKBAZ.IR

ESOPHAGOMYOTOMY. A surgical incision through the muscular tissue of the esophagus.

ESOPHAGOSCOPY. Looking down the esophagus with a flexible viewing instrument.

ESOPHAGUS. The muscular tube that leads from the back of the throat to the stomach. Coated with mucus and surrounded by muscles, it pushes food to the stomach by contraction.

ESSENCE. The constituent of a plant that determines its characteristics.

ESSENTIAL FATTY ACID. A type of fat that is necessary for the normal function of the brain and body and that the body is unable to produce itself, making them essential to be taken in through diet.

ESSENTIAL HEALTH BENEFITS (EHB). Minimum services that must be provided by health insurance plans under the PPACA.

ESSENTIAL OIL. A volatile oil extracted from the leaves, fruit, flowers, roots, or other components of a plant and used in aromatherapy, perfumes, and foods and beverages.

ESSENTIAL TREMOR. An uncontrollable (involuntary) shaking of the hands, head, and face. Also called familial tremor because it is sometimes inherited; it can begin in the teens or in middle age. The exact cause is not known.

ESTRODIOL. The most physiologically active form of estrogen.

ESTROGEN. Any of several naturally occurring or synthetic steroid hormones that promote the growth and maintenance of the female reproductive system.

ESTROGEN RECEPTOR (ER). A protein on the surface of cells that binds the female hormone estrogen, initiating estrogenic effects, and present on ER-positive breast cancer cells.

ESTROGEN REPLACEMENT THERAPY. Use of the female hormone estrogen to replace that which the body no longer produces naturally after medical or surgical menopause.

ETHANOL. The chemical name for beverage alcohol. It is also sometimes called ethyl alcohol or grain alcohol to distinguish it from isopropyl or rubbing alcohol.

ETHINYL ESTRADIOL. A semi-synthetic derivative of estradiol—an estrogen or female sex hormone—used in birth control pills and combined ECPs.

ETHMOID SINUSES. Paired labyrinth of air cells between the nose and eyes.

EUKARYOTE. Any organism with cells that contain a nucleus and organelles enclosed within membranes. Fungi are eukaryotes that lack chlorophyll.

EUNUCH. A castrated male, often one castrated at an early age with noticeable hormonal consequences.

EUPHORIA. An exaggerated state of psychological and physical well-being.

EUSTACHIAN TUBE. A thin tube between the middle ear and the pharynx. Its purpose is to equalize pressure on either side of the eardrum.

EUSTRESS. A term that is sometimes used to refer to positive stress.

EUTHANASIA. The act of putting a person or animal to death painlessly or allowing them to die by withholding medical services, usually because of a painful and incurable disease.

EUTHYROID. Having the right amount of thyroxin stimulation.

EVENT RECORDER. A small machine, worn by a patient usually for several days or weeks, that is activated by the patient to record his or her EKG when a symptom is detected.

EVIDENCE-BASED MEDICINE. Recommendations that are based on an evaluation of randomized, controlled trials; non-randomized trials; other experiments; descriptive studies; and reports of expert committees. Each class of evidence is graded (A to D, with A being the most reliable) based on the type and size of study. Recommendations and clinical practice guides can then be made using these grades.

EVISERATED. Removal of eye contents.

EVOKED POTENTIALS. Tests that measure the brain's electrical response to stimulation of sensory organs (eyes or ears) or peripheral nerves (skin). These tests may help confirm the diagnosis of multiple sclerosis.

EVULSION. The forceful, and usually accidental, removal of a tooth from its socket in the bone.

EX UTERO INTRAPARTUM TREATMENT (EXIT). A cesarean section in which the infant is removed from the uterus but the umbilical cord is not cut until after surgery; treats congenital defects that block an air passage.

EXANTHEM. A skin eruption regarded as a characteristic sign of such diseases as measles, German measles, and scarlet fever.

EXCESSIVE DAYTIME SLEEPINESS (EDS). A persistent sense of mental cloudiness, a lack of energy, a depressed mood, or extreme state of exhaustion.

EXCHANGES. American Health Benefit Exchanges; state systems through which individuals can compare and purchase health insurance under the PPACA.

EXCIMER LASER. An instrument that is used to vaporize tissue with a cold, coherent beam of light with a single wavelength in the ultraviolet range.

EXCISIONAL BIOPSY. Removal of an entire lymph node; often the most suspicious-looking node is removed for testing.

EXECUTIVE FUNCTIONS. An umbrella term for the group of mental processes responsible for planning, abstract thinking, logical deduction, choosing appropriate behaviors and inhibiting inappropriate behaviors, and distinguishing between relevant and irrelevant sensory information.

EXERCISE-INDUCED ASTHMA (EIA). Asthma attacks caused by aerobic exercise.

EXOCRINE. A system of organs that produces chemicals that go through a duct (or tube) to reach other organs whose functioning they affect.

EXOPHTHALMOS. A condition in which the eyes bulge out of their sockets and inhibit proper eyelid function.

EXOSTOSIS (PLURAL, EXOSTOSES). A lump that forms on the outside of a bone due to excess calcium formation. Exostoses commonly form close to joints and can cause considerable chronic pain.

EXOTOXIN. A poisonous secretion produced by bacilli which is carried in the bloodstream to other parts of the body.

EXPECTORANT. Drug used to thin mucus.

EXPEDITED PARTNER THERAPY (EPT). A preventive measure that allows a doctor to prescribe or give medications to an infected patient's partner without having to first examine the partner for an STI.

EXPOSURE SCIENCE. The study of the ways in which environmental factors can affect human health.

EXPOSURE THERAPY. An approach to treating trauma survivors that helps them to cope with trauma-related thoughts, feelings, and situations by exposing them to these reminders of the trauma in a safe situation.

EXSTROPHY. Being turned inside out combined with being outside the body.

EXTENDED FAMILY FIELD. A person's family of origin plus grandparents, in-laws, and other relatives.

EXTENSIVELY DRUG-RESISTANT (XDR). Bacteria that are resistant to many antibiotics.

EXTENSOR MUSCLES. A group of muscles in the forearm that serve to lift or extend the wrist and hand. Tennis elbow results from overuse and inflammation of the tendons that attach these muscles to the outside of the elbow.

EXTERNAL RADIATION THERAPY. Radiation therapy delivered from a source external to the body such as from a radiation therapy machine.

EXTERNALIZING DISORDERS. Disorders in which a person acts out inner turmoil or conflict on the external environment. The three major characteristics of externalizing disorders are disruptive, hyperactive, and aggressive behaviors.

EXTRACORPOREAL. Outside of, or unrelated to, the body.

EXTRACORPOREAL CIRCUIT (ECC). The path the hemodialysis patient's blood takes outside of the body. It typically consists of plastic tubing, a hemodialysis machine, and a dialyzer.

EXTRACORPOREAL SHOCK WAVE LITHOTRIPSY (ESWL). The use of focused shock waves, generated outside the body, to fragment kidney stones.

EXTRACTION. The surgical removal of a tooth from its socket in the bone.

EXTRACTION SITE. The empty tooth socket following removal of a tooth.

EXTRAGONADAL. In a location other than the reproductive organs.

EXTRAGONADAL. In a location other than the reproductive organs.

EXTRAOCULAR MUSCLES. The muscles (lateral rectus, medial rectus, inferior rectus, superior rectus, superior oblique, and inferior oblique) that move the eyeball.

EXTRAOCULAR RETINOBLASTOMA. Cancer that has spread from the eye to other parts of the body.

EXTRAPYRAMIDAL SYMPTOMS (EPS). A group of side effects associated with antipsychotic medications. EPS

WWW.BOOKBAZ.IR

include parkinsonism, akathisia, dystonia, and tardive dyskinesia.

EXTRINSIC PATHWAY. One of three pathways in the coagulation cascade.

EXTUBATION. Removal of a breathing tube.

EXUDATE. Cells, protein, fluid, or other material that passes through blood vessel walls and accumulates in the surrounding tissue.

F

FACE LIFT. Plastic surgery performed to remove sagging skin and wrinkles from an individual's face.

FACE MASK. The simplest way of delivering a high level of oxygen to patients with ARDS or other low-oxygen conditions.

FACEBOOK DEPRESSION. A term used to describe an adolescent mood disorder associated with low self-esteem and depressed mood triggered by excessive concern with online social media.

FACIAL NERVE. A cranial nerve that controls the muscles in the face.

FACIOSCAPULOHUMERAL MUSCULAR DYSTROPHY (FSH). This form of muscular dystrophy, also known as Landouzy–Dejerine condition, begins in late childhood to early adulthood and affects both men and women, causing weakness in the muscles of the face, shoulders, and upper arms.

FACTITIOUS DISEASES. Conditions in which symptoms are deliberately manufactured by patients in order to gain attention and sympathy. Patients with factitious diseases do not fake symptoms for obvious financial gain or to evade the legal system.

FACTITIOUS DISORDER. A disorder in which the physical or psychological symptoms are under voluntary control.

FACTOR. Any of several substances necessary to produce a result or activity in the body. The term is used when the chemical nature of the substance is unknown. In endocrinology, when the chemical nature is known, factors are renamed hormones.

FACTOR VIII. A protein involved in blood clotting that requires vWF for stability and long-term survival in the bloodstream.

FACTORS. Coagulation factors are substances in the blood, such as proteins and minerals, that are necessary for clotting. Each clotting substance is designated with roman numerals I through XIII.

FACTORY FARMING. A term that refers to the application of techniques of mass production borrowed from industry to the raising of livestock, poultry, fish, and crops. It is also known as industrial agriculture.

FAGET'S SIGN. The simultaneous occurrence of a high fever with a slowed heart rate.

FALLOPIAN TUBES. The tubes that carry the ovum (egg) from the ovary to the uterus.

FALSE NEGATIVE. Test results showing no problem when one exists.

FALSE POSITIVE. Test results showing a problem when one does not exist.

FAMCICLOVIR. An oral antiviral drug that blocks the replication of the varicella zoster virus.

FAMILIAL ADENOMATOUS POLYPOSIS (FAP). An inherited disease characterized by numerous polyps in the colon and rectum that usually become cancerous.

FAMILY-SYSTEMS THEORY. An approach to treatment that emphasizes the interdependency of family members rather than focusing on individuals in isolation from the family. This theory underlies the most influential forms of contemporary family therapy.

FANCONI SYNDROME. A kidney disorder in which glucose, amino acids, uric acid, phosphate, and bicarbonate are passed into the urine instead of being reabsorbed into the blood.

FANCONI'S ANEMIA. An inherited form of aplastic anemia.

FANCONI'S SYNDROME. A rare disorder caused by vitamin D deficiency or exposure to heavy metals.

FARMER'S LUNG. An allergic reaction to moldy hay, most often seen in farmers, that results in lung disease.

FASCIA. Thin connective tissue covering or separating the muscles and internal organs of the body.

FASCIA, DEEP. A fibrous layer of tissue that envelopes muscles.

FASCIA, SUPERFICIAL. A fibrous layer of tissue that lies between the deepest layer of skin and the subcutaneous fat.

FASCICULATIONS. Involuntary twitching of patient's muscles.

FASCIOTOMY. Surgical removal of strips of fascia to relieve pressure in the compartment.

FAST. A period of at least 24 hours in which a person eats nothing and drinks only water.

FAT. Molecules composed of fatty acids and glycerol; the slowest utilized source of energy, but the most energy-efficient form of food. Each gram of fat supplies about nine calories, more than twice that supplied by the same amount of proteins or carbohydrates.

FAT-SOLUBLE VITAMIN. A vitamin that dissolves in fat and can be stored in body fat or the liver.

FATTY ACIDS. Complex molecules found in fats and oils. Essential fatty acids are fatty acids that the body needs but cannot synthesize. Essential fatty acids are made by plants and must be present in the diet to maintain health.

FATTY LIVER. An abnormal amount of fat tissue in the liver caused by alcohol abuse.

FEBRILE SEIZURE. Convulsions brought on by fever.

FECAL IMMUNOCHEMICAL TESTING (FIT). Antibody testing for blood in a stool sample.

FECAL IMPACTION. Obstruction of the rectum by a large mass of feces (stool).

FECAL OCCULT BLOOD TESTING (FOBT). Laboratory testing for blood in a stool sample.

FECES. (Also called stool.) The solid waste that is left after food is digested. Feces form in the intestines and pass out of the body through the anus.

FEDERAL POVERTY LEVEL (FPL). The U.S. government's definition of poverty for families of a given size, adjusted annually for inflation and used as the reference point for determining eligibility for Medicaid and health insurance subsidies under the PPACA.

FELDENKRAIS METHOD. A therapy based on creating a good self image by correction and improvements of body movements.

FELTY'S SYNDROME. An autoimmune disorder in which neutropenia is associated with rheumatoid arthritis and an enlarged spleen.

FEMALE ATHLETE TRIAD. A combination of disorders frequently found in female athletes that includes disordered eating, osteoporosis, and oligo- or amenorrhea. The triad was first officially named in 1993.

FEMALE STERILIZATION. The process of permanently ending a woman's ability to conceive by tying off or cutting apart the fallopian tubes.

FEMORAL ARTERY. The chief artery of the thigh.

FEMUR. The thigh bone.

FENTANYL. A synthetic opioid narcotic pain reliever with effects similar to morphine but many times stronger.

FERRITIN. A protein found in the liver, spleen, and bone marrow that stores iron.

FERTILIZATION. The joining of the sperm and the egg; conception.

FETAL. Refers to the fetus, also known in the first two months after conception as an embryo.

FETAL ALCOHOL SPECTRUM DISORDERS. A range of birth defects, including intellectual disability, poor growth, nervous system dysfunctions, and malformations, that result from heavy maternal alcohol consumption during pregnancy.

FETAL ALCOHOL SYNDROME. A cluster of birth defects that includes abnormal facial features and intellectual disabilities (ID), caused by the mother's consumption of alcoholic beverages during pregnancy.

FETAL TISSUE TRANSPLANTATION. A method of treating Parkinson's and other neurological diseases by grafting brain cells from human fetuses onto the basal ganglia. Human adults cannot grow new brain cells but developing fetuses can. Grafting fetal tissue stimulates the growth of new brain cells in affected adult brains.

FETOSCOPE. A fiber-optic instrument for viewing the fetus inside the uterus.

FETUS. Term for an unborn baby after the eighth week of pregnancy. Prior to seven weeks, it is called an embryo.

FIBER. Also known as roughage or bulk. Insoluble fiber moves through the digestive system almost undigested and gives bulk to stools. Soluble fiber dissolves in water and helps keep stools soft.

FIBEROPTICS. In medicine, fiberoptics uses glass or plastic fibers to transmit light through a specially designed tube inserted into organs or body cavities where it transmits a magnified image of the internal body structures.

FIBRILLATION. Rapid, uncoordinated contractions of the upper or the lower chambers of the heart.

FIBRILLIN. A protein that is an important part of the structure of the body's connective tissue. In Marfan's syndrome, the gene responsible for fibrillin has mutated, causing the body to produce a defective protein.

WWW.BOOKBAZ.IR

FIBRIN. A fibrous blood protein vital to coagulation and blood clot formation.

FIBRIN SPLIT PRODUCTS (FSP). Pieces of the protein fibrin released from a dissolving clot.

FIBRINOGEN. A blood protein that interacts with thrombin to form fibrin.

FIBRINOLYSIS. The clot dissolving portion of the coagulation process.

FIBROADENOMA. A benign breast growth made up of fibrous tissue. It is the most common mass in women under 35 years of age, and is found in both breasts in 3% of cases.

FIBROBLAST. A large flat cell that secretes the proteins that form collagen and elastic fibers and the substance between the cells of connective tissue.

FIBROID TUMORS. Fibroid tumors are non-cancerous (benign) growths in the uterus. They occur in 30-40% of women over age 40, and do not need to be removed unless they are causing symptoms that interfere with a woman's normal activities.

FIBROMA. A usually benign tumor consisting of fibrous tissue.

FIBROMUSCULAR DYSPLASIA. A disorder that causes unexplained narrowing of arteries and high blood pressure.

FIBROMYALGIA. A chronic syndrome characterized by fatigue, widespread muscular pain, and pain at specific points on the body.

FIBROSIS. The formation of fibrous, or scar, tissue that may follow inflammation and destruction of normal tissue.

FIBROTIC. Pertaining to or characterized by fibrosis. In dermatological description, "fibrotic" would be used to describe leathery, bound-down, or thickened, scarred skin.

FIBROUS CONNECTIVE TISSUE. Dense tissue found in various parts of the body containing very few living cells.

FIBULA. The smaller of the two bones in the lower leg.

FIFTH DISEASE. Erythema infectiosum; a common respiratory infection among children caused by parvovirus B19 that usually is not serious but can cause fetal complications.

FILARIAL. Threadlike. The word "filament" is formed from the same root word.

FILARIASIS. A tropical disease caused by worms that live in lymph channels.

FILARIFORM. Threadlike in appearance, like the infectious stage of the threadworm larva.

FILLING. Dental material that occupies the space remaining within a tooth after the decayed portion has been removed.

FILOVIRUSES. The family of viruses that includes Ebola and hemorrhagic-fever viruses.

FILTRATE. The medical term for the water and small molecules filtered in the nephron of the kidney.

FINE NEEDLE ASPIRATION. Removal of tissue or suspensions of cells using a small needle.

FINGER STICK. A technique for collecting a very small amount of blood from the fingertip area.

FIRST SPACE. The intracellular fluid in the body (ICF).

FISSURE. A deep crack.

FISTULA. An abnormal passage.

FLACCID. Weak, soft, or floppy.

FLACCID PARALYSIS. Paralysis characterized by limp, unresponsive muscles.

FLAGELLATE. A microorganism that uses flagella (hair-like projections) to move.

FLAGELLUM. A tail-like projection extending from the cell walls of certain bacteria. Its name is the Latin word for "whip.".

FLAP. A section of tissue moved from one area of the body to another.

FLARE. A recurrence or worsening of the symptoms of JA.

FLARE AND CELL. A pattern revealed by slit-lamp examination that indicates uveitis. Flare and cell resembles light filtered through smoke.

FLASHBACK. The reemergence of a traumatic memory as a vivid recollection of sounds, images, and sensations associated with the trauma. The person having such a memory typically feels as if he or she is reliving the event.

FLATULENCE. Excess gas in the digestive tract.

FLATUS. Gas or air in the digestive tract.

FLAVIVIRUS. An arbovirus that can cause potentially serious diseases, such as dengue, yellow fever, zika fever, and West Nile fever.

FLAVONOID. A food chemical that helps to limit oxidative damage to the body's cells and protects against heart disease and cancer.

FLAXSEED. Linseed; the seed of flax, *Linum usitatissimum*, used as a source of oil for treating inflammation of the respiratory, intestinal, and urinary tracts, and as a dietary supplement.

FLEX. To bend.

FLEXION. A bending motion or position that decreases the angle between two body parts. Volkmann's contracture is a flexion contracture of the hand.

FLOATERS. Translucent specks that float across the visual field, due to small objects floating in the vitreous humor.

FLORA. Refers to normal bacteria found in a healthy person.

FLOW METER. Device for measuring the rate of a gas (especially oxygen) or liquid.

FLUENCY. The ability to produce a flow of words and not get stuck. Stuttering is an example of a fluency problem.

FLUKE. A parasitic flatworm that has external suckers. Flukes are sometimes called trematodes.

FLUORESCEIN. A fluorescent chemical used to examine the cornea.

FLUORESCEIN DYE. An orange dye used to illuminate the blood vessels of the retina in fluorescein angiography.

FLUORESCENCE IN SITU HYBRIDIZATION (FISH). Technique used to detect small deletions or rearrangements in chromosomes.

FLUORESCENT ANTIBODY TEST (FA TEST). A test in which a fluorescent dye is linked to an antibody for diagnostic purposes.

FLUORIDE. A chemical compound containing fluorine that is used to treat water or applied directly to teeth to prevent decay.

FLUOROQUINOLONES. A relatively new group of antibiotics that have had good success in treating infections with many gram-negative bacteria, such as *Shigella*. One drawback is that they should not be used in children under 17 years of age because of possible effects on bone and cartilage growth.

FLUOROSCOPY. A diagnostic imaging procedure that uses x rays and contrast agents to visualize anatomy and motion in real time.

FLUOROURACIL. A cancer drug.

FLUOXETINE. The first SSRI; marketed as Sarafem for treating PMDD.

FLUVOXAMINE. An SSRI that is used to treat obsessive-compulsive disorder as well as other conditions.

FMR-1 GENE. A gene found on the X chromosome. Its exact purpose is unknown, but it is suspected that the gene plays a role in brain development.

FOLATE. One of the B vitamins, also called folic acid.

FOLEY CATHETER. A double-channel retention catheter; one channel provides for the inflow and outflow of bladder fluid, the second (smaller) channel is used to fill a balloon that holds the catheter in the bladder.

FOLIC ACID. Folate; vitamin B_9.

FOLLICLE. The small sac at the base of a hair shaft. The follicle lies below the skin surface.

FOLLICLES. Structures in the skin containing oil glands and hair; the source of pimples.

FOLLICLE-STIMULATING HORMONE (FSH). The pituitary hormone that stimulates the ovary to mature egg capsules (follicles). It is linked with rising estrogen production throughout the cycle. An elevated FSH (above 40) indicates menopause.

FOLLICULAR. Relating to one of the round cells in the ovary that contain an ovum.

FOMITE. An inanimate object that can transmit infectious organisms.

FONTANEL. One of the membranous intervals between the uncompleted angles of the parietal and neighboring bones of a fetal or young skull; so called because it exhibits a rhythmical pulsation.

FOOD IRRADIATION METHODS. A process using radiant energy to kill microorganisms in food, to extend the amount of time in which food can be sold and eaten safely.

FOOD-BORNE ILLNESS. A disease that is transmitted by eating or handling contaminated food.

FOOTLING BREECH. A position of the fetus while in the uterus where the feet of the fetus are nearest the cervix and will be the first part of the fetus to exit the uterus, with the head of the fetus being the last part to exit the uterus.

FORAMEN. The medical term for a natural opening or passage

WWW.BOOKBAZ.IR

FORAMEN MAGNUM. The opening at the base of the skull, through which the spinal cord and the brain stem pass.

FORAMEN OVALE. The foramen ovale, a fetal cardiac structure that allows the blood in both upper chambers (atria) of the heart to mix. After birth, the pressure rises in the left atrium pushing this opening closed, allowing the heart to function in a two-sided fashion: the right side carries the unoxygenated blood to the lungs, and the left side pumps the oxygenated blood out into the body.

FORAMINOTOMY. Surgery to take pressure off nerves in a foramen; often combined with disk removal.

FORCED EXPIRATORY VOLUME (FEV). The volume of air exhaled from the beginning of expiration to a set time (usually 0.5, 1, 2, and 3 seconds).

FORCED EXPIRATORY VOLUME (FEV1). The maximum volume of air that the patient can forcibly blow out in the first second during the forced vital capacity (FVC) test.

FORCED VITAL CAPACITY (FVC). A measurement of the volume of air that the patient can exhale from the lungs after taking a deep breath. To measure the FVC, the patient is asked to take the deepest breath they can and then exhale into a sensor as hard as possible for as long as possible.

FORCIBLE SODOMY. Forced oral or anal intercourse.

FOREMILK. Thin watery milk found at the beginning of breast feeding.

FORENSIC. Pertaining to or used during legal proceedings.

FORESKIN. A covering fold of skin over the tip of the penis.

FORMALIN. A clear solution of diluted formaldehyde that is used to preserve liver biopsy specimens until they can be examined in the laboratory.

FORTIFIED. Altered by addition of vitamins or minerals.

FOVEA. A small area of the retina responsible for acute vision.

FRACTIONATION. A procedure for dividing a dose of radiation into smaller treatment doses.

FRACTURE. A break or crack in a bone.

FRAGILE X SYNDROME. A genetic condition related to the X chromosome that affects mental, physical, and sensory development.

FRAGILITY FRACTURE. A fracture that occurs as a result of a fall from standing height or less. A person with healthy bones would not suffer a broken bone falling from a standing position.

FREE FLAP. A section of tissue is detached from its blood supply, moved to another part of the body, and reattached by microsurgery to a new blood supply.

FREE FLAP FACIAL SURGERY. Facial reconstruction using skin obtained from another part of the patient's body.

FREE-FLOATING ANXIETY. Anxiety that lacks a definite focus or content.

FREE RADICAL. A molecule with an unpaired electron that has a strong tendency to react with other molecules in deoxyribonucleic acid (DNA), proteins, and lipids (fats), resulting in damage to cells. Free radicals are neutralized by antioxidants.

FREEGAN. A vegan who obtains food outside the mainstream economic system, most often by growing it, bartering for it, or scavenging for it in restaurant or supermarket trash bins.

FREQUENCY. Sound, whether traveling through air or the human body, produces vibrations—molecules bouncing into each other—as the shock wave travels along. The frequency of a sound is the number of vibrations per second. Within the audible range, frequency means pitch—the higher the frequency, the higher a sound's pitch.

FRICTION. The resistance to motion such as that caused by a stationary surface being subjected to a moving surface.

FRONTAL LOBE. The largest, most forward-facing part of each side or hemisphere of the brain.

FROZEN SHOULDER. A shoulder that becomes scarred and cannot move.

FRUCTOSE. A monosaccharide found in many fruits.

FRUITARIAN. A vegetarian who eats only plant-based products, such as fruits, seeds, and nuts, that can be obtained without killing the plant.

FUCHS' DYSTROPHY. A hereditary disease of the inner layer of the cornea. Treatment requires penetrating keratoplasty. The lens of the eye may also be affected and require surgical replacement at the same time as the cornea.

FUGUE. A dissociative experience during which a person travels away from home, has amnesia for their

past, and may be confused about their identity but otherwise appear normal.

FULMINANT. Referring to any medical event that develops quickly and explosively, and is severe and potentially lethal. The English word comes from the Latin word for lightning.

FULMINATING COLITIS. A potentially fatal complication of amebic dysentery marked by sudden and severe inflammation of the intestinal lining, severe bleeding or hemorrhaging, and massive shedding of dead tissue.

FUNCTIONAL CYST. A benign cyst that forms on the ovary and resolves on its own without treatment.

FUNCTIONAL FOOD. Also called nutraceuticals, these products are marketed as having health benefits or disease-preventing qualities beyond their basic supply of energy and nutrients. Often these health benefits come in the form of added herbs, minerals, vitamins, etc.

FUNCTIONAL MAGNETIC RESONANCE IMAGING. A special type of magnetic resonance imaging (MRI) scan that measures changes in blood flow and blood oxygenation within the body; often abbreviated fMRI.

FUNCTIONAL PAIN. Pain that does not have a structural or organic cause.

FUNCTIONAL RESIDUAL CAPACITY (FRC). The volume of air left in the lungs at the end of passive expiration (breathing out). It can be measured by body plethysmography.

FUNDOPLICATION. A surgical procedure that tightens the lower esophageal sphincter by stretching and wrapping the upper part of the stomach around the sphincter.

FUNDOPLICATION. A surgical procedure that tightens the lower esophageal sphincter by stretching and wrapping the upper part of the stomach around the sphincter.

FUNDUS. The inside of an organ. In the eye, refers to the back area that can be seen with the ophthalmoscope.

FUNGAL. Caused by a fungus, a member of a group of simple organisms that are related to yeast and molds.

FUNGUS. A unicellular or filamentous organism that causes parasitic infections.

FUNNEL BREAST (ALSO KNOWN AS PECTUS EXCAVATUM). A condition where there is a hollow depression in the lower part of the chest.

FURUNCULOSIS. A condition in which the patient suffers from recurrent episodes of boils.

FUSION. A union or joining together of materials (e.g., bone fusion).

G

G SUITS. Special flight suits, worn by fighter pilots, which have compartments that fill with air or fluid to keep blood from pooling in the lower body during rapid acceleration and tight turns.

GADOLINIUM. A very rare metallic element useful for its sensitivity to electromagnetic resonance, among other things. Traces of it can be injected into the body to enhance the MRI pictures.

GAG REFLEX. A normal reflex consisting of elevation of the palate, retraction of the tongue, and contraction of the throat muscles.

GAIN-OF-FUNCTION (GOF). Research aimed at making viruses that are easier to transmit or cause more serious disease, in order to recognize such strains if they emerge and design better treatments and vaccines.

GALACTORRHEA. Excessive or spontaneous flow of milk.

GALACTOSE. One of the two simple sugars, together with glucose, that makes up the protein, lactose, found in milk. Galactose can be toxic in high levels.

GALACTOSEMIA. A rare genetic disorder where an infant cannot metabolize the sugar in breast milk, and therefore cannot breastfeed.

GALLBLADDER. A small, pear-shaped organ in the upper right hand corner of the abdomen. It is connected by a series of ducts (tube-like channels) to the liver pancreas, and duodenum (first part of the small intestine). The gallbladder receives bile from the liver and concentrates and stores it. After a meal, bile is squeezed out of the gallbladder into the intestine, where it aids in digestion of food.

GALLIUM. A form of radionuclide that is used to help locate tumors and inflammation (specifically referred to as GA67 citrate).

GALLOP RHYTHM. An abnormal heart rhythm in which the doctor can hear three (sometimes four) sounds instead of the usual two, resembling the rhythm of a horse's gallop.

WWW.BOOKBAZ.IR

GALLSTONE. Hardened deposits of digestive fluid that can form in the gallbladder.

GALLSTONE ILEUS. Obstruction of the large intestine caused by a gallstone that has blocked the intestinal opening.

GAMETE. An egg (ovum) from the female or a mature sperm from the male.

GAMMA CAMERA. A device inside the SPECT machine that forms images of the gamma rays emitted by the radionuclides used in tracers in nuclear medicine.

GAMMA GLOBULIN. One of a group of proteins found in the blood that is involved in helping the body fight infections.

GAMMA KNIFE. A surgical tool that focuses beams of radiation at the head, which converge in the brain to form a lesion.

GAMMA RAY. Short wavelength, high energy electromagnetic radiation emitted by radioactive substances.

GAMMA-GLOBULIN. An extract of human blood that contains antibodies.

GANGLION. A mass of nerve tissue outside of the central nervous system.

GANGLIONEUROMA. A ganglioneuroma is a tumor composed of mature nerve cells.

GANGLIOSIDE. A fatty (lipid) substance found within the brain and nerve cells.

GANGRENE. A decay or death of the tissue in a part of the body that experiences restricted blood flow.

GANSER'S SYNDROME. An unusual factitious disorder characterized by dissociative symptoms and absurd answers to direct questions.

GANTRY. A name for the couch or table used in a CT scan. The patient lies on the gantry while it slides into the x-ray scanner portion.

GAS CHROMATOGRAPHY. A method for separating the various chemicals in a test sample by vaporizing a portion of a sample, mixing it with a carrier gas (usually nitrogen), and passing the mixture through a long column of adsorbent material. The different chemicals in the sample will pass through the column at different rates of speed and can then be identified.

GAS EMBOLISM. The presence of gas bubbles in the bloodstream that obstruct circulation. Also called air embolism.

GAS EXCHANGE. The process by which oxygen is extracted from inhaled air into the bloodstream, and, at the same time, carbon dioxide is eliminated from the blood and exhaled.

GAS GANGRENE. A severe form of gangrene caused by *Clostridium* infection.

GASTRIC. Relating to the stomach.

GASTRIC (OR PEPTIC) ULCER. An ulcer (sore or hole) in the stomach lining, duodenum, or other part of the gastrointestinal system.

GASTRIC GLANDS. Branched tubular glands located in the stomach.

GASTRIC LAVAGE. Also called a stomach pump. For this procedure, a flexible tube is inserted through the nose, down the throat, and into the stomach and the contents of the stomach are suctioned out. The inside of the stomach is rinsed with a saline (salt water) solution.

GASTRIC PACING. An experimental form of obesity surgery in which electrodes are implanted in the muscle of the stomach wall. Electrical stimulation paces the timing of stomach contractions so that the patient feels full on less food.

GASTRIC ULCER. An ulcer of the stomach, duodenum, or other part of the gastrointestinal system. Also called a peptic ulcer.

GASTRIN. A hormone secreted in the stomach that is involved in the production of gastric acid. Overproduction of gastric acid contributes to peptic ulcer formation.

GASTRINOMA. Tumor that arises from the gastrin-producing cells in the pancreas.

GASTROENTERITIS. An inflammation of the lining of the stomach and intestines, usually caused by a viral or bacterial infection.

GASTROENTEROLOGIST. A physician who specializes in diseases of the digestive system.

GASTROESOPHAGEAL REFLUX. Condition in which stomach acid backs up into the esophagus.

GASTROESOPHAGEAL REFLUX DISEASE (GERD). Recurrent heartburn or acid indigestion caused by leakage of the stomach contents into the esophagus.

GASTROINTESTINAL. The digestive organs and structures, including the stomach and intestines.

GASTROINTESTINAL TRACT. A group of organs and related structures that includes the esophagus,

stomach, liver, gallbladder, pancreas, small intestine, large intestine, rectum, and anus.

GASTROJEJUNOSTOMY. A surgical procedure in which the stomach is surgically connected to the jejunum (middle portion of the small intestine).

GASTROPLASTY. A surgical procedure used to reduce digestive capacity by shortening the small intestine or shrinking the side of the stomach.

GASTROSCOPY. Looking into the stomach with a flexible viewing instrument called a gastroscope.

GASTROSTOMY. Surgical creation of an artificial opening into the stomach through the abdominal wall to allow tube feeding.

GASTROSTOMY TUBE. Stomach tube for feeding.

GAUCHER'S DISEASE. A rare genetic disease caused by a deficiency of enzymes needed for the processing of fatty acids.

GBS. Group B streptococci are a type of bacteria that, if passed to an infant, can cause inflammation of the brain, spinal cord, blood, or lungs. In some cases, it can result in infant death.

GELASTIC SEIZURES. Seizures manifesting with brief involuntary laughter.

GENDER DYSPHORIA. Persistent personal discomfort with one's present biological sex.

GENE. A building block of inheritance, made up of a compound called DNA (deoxyribonucleic acid) and containing the instructions for the production of a particular protein. Each gene is found on a specific location on a chromosome.

GENE THERAPY. A method of treating a disorder by replacing damaged or abnormal genes with normal ones.

GENERAL ANESTHESIA. Deep sleep induced by a combination of medicines that allows surgery to be performed.

GENERAL PARESIS. An advanced form of neurosyphilis affecting personality and control of movement and possibly causing convulsions or partial paralysis.

GENERAL SURGERY. General surgery includes procedures on the abdominal cavity organs and other body areas such as breast and thyroid. It also includes procedures on various other body regions that may be associated with multiple specialties.

GENETIC. The term refers to genes, the basic units of biological heredity, which are contained on the chromosomes and contain chemical instructions that direct the development and functioning of an individual.

GENETIC CLUSTER. A group of viral strains with very similar, yet distinct, nucleic acid sequences.

GENETIC DISEASE. A disease caused by genes inherited from one or both parents.

GENETIC ENGINEERING. A type of engineering that concentrates on the process of altering genetic material by technical means.

GENETIC HETEROGENEITY. The occurrence of the same or similar disease, caused by different genes among different families.

GENETICS. The study of genes and biological inheritance.

GENIOPLASTY. An operation performed to reshape the chin. Genioplasties are often done to treat OSA because the procedure changes the structure of the patient's upper airway.

GENITAL HERPES. A sexually-transmitted disease caused by the herpes simplex virus.

GENITALS. The reproductive organs in either sex, especially the external reproductive organs.

GENOGRAM. A family tree diagram that represents the names, birth order, sex, and relationships of the members of a family. Therapists use genograms to detect recurrent patterns in the family history and to help the members understand their problem(s).

GENOGROUP. Related viruses within a genus; may be further subdivided into genetic clusters.

GENOME. The genetic makeup of a cell, composed of DNA.

GENOTYPE. The genetic makeup of a cell or organism. There are six genotypes of the virus that causes hepatitis C.

GENU VALGUM. Deformity in which the legs are curved inward so that the knees are close together, nearly or actually knocking as a person walks with ankles widely apart of each other.

GENUINE URINARY STRESS INCONTINENCE (USI). Stress incontinence due to hypermobility of the urethra.

GEOPHAGIA. The compulsive eating of earthy substances, including sand, soil, and clay.

GERIATRICS. The scientific field that focuses on studying the physical, mental, and social health of aging.

WWW.BOOKBAZ.IR

GERM. A disease-causing microorganism.

GERM CELL. One of the cells that ordinarily develops into eggs or sperm (also sperm and eggs).

GERM THEORY OF DISEASE. The theory that a specific microorganisms cause a specific disease.

GERMINOMA. A tumor of germ cells (ovum and sperm cells that participate in production of the developing embryo).

GERONTOLOGY. The scientific field that focuses on studying the physical, mental, and social health of aging.

GESTALT THERAPY. A humanistic therapy technique that focuses on gaining an awareness of emotions and behaviors in the present rather than in the past.

GESTATION. The period from conception to birth, during which the developing fetus is carried in the uterus.

GESTATIONAL AGE. The estimated age of a fetus expressed in weeks, calculated from the first day of the last normal menstrual period.

GESTATIONAL DIABETES MELLITUS. The occurrence of high blood glucose levels in pregnant, previously non-diabetic women.

GESTATIONAL TROPHOBLASTIC DISEASE. A rare, aggressive, malignant, often metastatic (spreading to other organs) cancer in women of childbearing age in which cancer cells grow in the tissues that are formed in the uterus after conception.

GHRELIN. A peptide hormone secreted primarily by the stomach that has been implicated in the control of food intake and fat storage.

GIANT CELL ARTERITIS. Also called temporal arteritis. A condition which causes the inflammation of temporal arteries. It can cause blindness when the inflammation effects the ophthalmic artery.

GIARDIA LAMBLIA. A type of protozoa with a whip-like tail that infects the human intestinal tract, causing giardiasis. The protozoa will not spread to other parts of the body.

GIARDIASIS. Parasitic infestation caused by a flagellate protozoan of the genus Giardia, especially by *Giardia lamblia* .

GIGANTISM. Excessive growth, especially in height, resulting from overproduction during childhood or adolescence of growth hormone by a pituitary tumor. Untreated, the tumor eventually destroys the pituitary gland, resulting in death during early adulthood. If the tumor develops after growth has stopped, the result is acromegaly, not gigantism.

GILBERT'S SYNDROME. A mild hereditary form of jaundice.

GILLBERG'S CRITERIA. A six-item checklist for Asperger syndrome developed by Christopher Gillberg, a Swedish researcher. It is widely used as a diagnostic tool.

GINGIVITIS. Inflammation of the gums, seen as painless bleeding during brushing and flossing.

GINKGO. An herb from *Ginkgo biloba*, a shade tree native to China with fan-shaped leaves and fleshy seeds with edible kernels. Some alternative practitioners recommend ginkgo extract for preventing and treating AD.

GLAND. A collection of cells whose function is to release certain chemicals, or hormones, which are important to the functioning of other, sometimes distantly located, organs or body systems.

GLANS. The cone-shaped tip of the penis.

GLASGOW COMA SCALE. A measure of the level of consciousness and neurological functioning after TBI.

GLAUCOMA. A condition in which pressure in the eye is abnormally high. If not treated, glaucoma may lead to blindness.

GLEASON GRADING SYSTEM. A method of predicting the tendency of a tumor in the prostate to metastasize based on the tumor's similarity to normal prostate tissue.

GLOBAL APHASIA. A condition characterized by either partial or total loss of the ability to communicate verbally or using written words as a result of widespread injury to the language areas of the brain. This condition may be caused by a stroke, head injury, brain tumor, or infection. The exact language abilities affected vary depending on the location and extent of injury.

GLOBIN. The protein component of hemoglobin.

GLOBULINS. A group of proteins in blood plasma whose levels can be measured by electrophoresis in order to diagnose or monitor a variety of serious illnesses.

GLOMERULAR KIDNEY DISEASE. Disease of the kidney that affects the glomeruli, the part of the kidney that filters certain substances out of the blood.

GLOMERULI. Knots of capillaries in the kidneys responsible for filtering the blood (singular, glomerulus).

GLOMERULONEPHRITIS. A disease of the kidney that causes inflammation and scarring and impairs the kidney's ability to filter waste products from the blood.

GLOSSOPHARYNGEAL NEURALGIA. Sharp recurrent pain deep in the throat that extends to the area around the tonsils and possibly the ear. It is triggered by swallowing or chewing.

GLOTTIS. The opening between the vocal cords at the upper part of the larynx.

GLUCOCEREBROSIDE. A cerebroside that contains glucose in the molecule.

GLUCOCORTICOID. A class of steroid hormones that are synthesized by the adrenal cortex and have anti-inflammatory activity.

GLUCOCORTICOID THERAPY. Treatment using corticoids that are anti-inflammatory and immunosuppressive.

GLUCOSE. A simple sugar that serves as the body's main source of energy.

GLUCOSE-6-PHOSPHATE DEHYDROGENASE (G6PD) DEFICIENCY. An inherited disorder in which the body lacks an enzyme that normally protects red blood cells from toxic chemicals. Certain drugs can cause patients' red blood cells to break down, resulting in anemia. This may also happen when they have a fever or an infection. The condition usually occurs in males. About 10% of black males have it, as do a small percentage of people from the Mediterranean region.

GLUTATHIONE. A molecule that acts as a co-enzyme in cellular oxidation-reduction reactions.

GLUTEN. A protein found in wheat, rye, barley, and oats.

GLUTEN ENTEROPATHY. A hereditary malabsorption disorder caused by sensitivity to gluten, a protein found in wheat, rye, barley, and oats. Also called nontropical sprue or Celiac disease.

GLYCEMIC INDEX (GI). A ranking from 1–100 of how much carbohydrate-containing foods raise blood sugar levels within two hours after being eaten. Foods with a glycemic index of 50 or lower are considered "good."

GLYCOGEN. A polysaccharide that is the principal source of stored glucose in humans

GLYCOGENOLYSIS. The process of tearing-down a glycogen molecule to free up glucose.

GLYCOGENOSIS. An alternate term for glycogen storage disease. The plural form is glycogenoses.

GLYCOLYSIS. The breakdown of glucose or glycogen to pyruvate to supply cellular energy.

GLYCOSURIA. Abnormal amounts of sugar in the urine.

GLYCOSYLATED HEMOGLOBIN. A test that measures the amount of hemoglobin bound to glucose. It is a measure of how much glucose has been in the blood during the past two to four months.

GNRH ANTAGONISTS. A group of medications that affect the reproductive hormones. These medications are used to treat fibroids, endometriosis, and infertility.

GOECKERMAN REGIMEN. UVB light therapy combined with topical coal-tar preparations.

GOITER. An abnormal enlargement of the thyroid gland.

GONAD. The organ that makes gametes (germ cells). The gonads in males are called "testicles" and produce sperm; those in females are called "ovaries" and produce eggs.

GONADOTROPHIN. Hormones that stimulate the ovary and testicles.

GONADOTROPINS. Hormones that stimulate the ovary and testicles.

GONADS. The reproductive organs; testes in males and ovaries in females.

GONIOMETER. An instrument for measuring angles of a joint.

GONIOSCOPE. An instrument used to inspect the eye (e.g., the anterior chamber). It consists of a magnifier and a lens equipped with mirrors; it's placed on the patient's cornea.

GONOCOCCUS (PLURAL, GONOCOCCI). The bacterium *Neisseria gonorrheae* that causes gonorrhea, a sexually transmitted infection of the genitals and urinary tract. Gonococci may occasionally affect the eye, causing blindness if not treated.

GONORRHEA. A sexually transmitted disease (STD) that causes infection in the genital organs and may cause disease in other parts of the body.

WWW.BOOKBAZ.IR

GONZALEZ REGIMEN. An alternative therapy for pancreatic cancer that includes a special diet, nutritional supplements, pancreatic enzymes, and coffee enemas.

GOUT. A disease in which uric acid, a waste product that normally passes out of the body in urine, collects in the joints and the kidneys.

GRAFT. To implant living tissue surgically. Graft also refers to the tissue that is transplanted.

GRAFT VERSUS HOST DISEASE. A life-threatening complication of bone marrow transplants in which the donated marrow causes an immune reaction against the recipient's body.

GRAINS. Flecks of hardened material such as bacteria or fungi spores.

GRAM STAIN. A staining procedure used to visualize and classify bacteria. The Gram stain procedure allows the identification of purple (Gram positive) organisms and red (Gram negative) organisms.

GRAM-NEGATIVE. Referring to bacteria that take on a pink color when exposed to Gram's stain.

GRAM-POSITIVE. Referring to bacteria that takes on a purplish-black color when exposed to Gram's stain.

GRANULATION TISSUE. A kind of tissue formed during wound healing, with a rough or irregular surface and a rich supply of blood capillaries.

GRANULE. A small grain or pellet. Medicines that come in granule form are usually mixed with liquids or sprinkled on food before they are taken.

GRANULES. Small packets of reactive chemicals stored within cells.

GRANULOCYTE. Any of several types of white blood cells that have granules in their cell substance.

GRANULOCYTE MACROPHAGE COLONY STIMULATING FACTOR (GM-CSF). Also known as sargramostim, a substance produced by cells of the immune system that stimulates an attack upon foreign cells. Used to treat prostate cancers as a genetically engineered component of a vaccine that stimulates the body to attack prostate tissue.

GRANULOCYTOPENIA. A condition characterized by a deficiency of white blood cells.

GRANULOMA. An inflammatory swelling or growth composed of granulation tissue.

GRANULOMATOUS. Resembling a tumor made of granular material.

GRANULOMATOUS DISEASE. Characterized by growth of tiny blood vessels and connective tissue.

GRANULOMATOUS MYOCARDITIS. Also called giant cell myocarditis, this noninfectious inflammation of the heart causes large areas of tissue death in the heart muscle, ventricular enlargement, and clots inside the heart chambers.

GRAVEL. The debris that is formed from a fragmented kidney stone.

GRAVES' DISEASE. An autoimmune disorder of the thyroid gland, in which the gland swells to twice its normal size and secretes too much thyroid hormone. It is named for an Irish doctor named Robert James Graves, who described a case of the disorder in 1835.

GRAY MATTER. The portion of the brain that contains neurons, as opposed to white matter, which contains nerve tracts.

GROIN. The region of the body that lies between the abdomen and the thighs.

GROUP A STREPTOCOCCUS. A sphere-shaped bacterium that grows in long chains and causes strep throat as well as scarlet fever and some forms of tonsillitis.

GROUP B STREPTOCOCCUS. A common bacterial infection that is potentially life-threatening if transmitted to a fetus during early pregnancy or delivery.

GROUP THERAPY. Group interaction designed to provide support, correction through feedback, constructive criticism, and a forum for consultation and reference.

GROWTH FACTOR. A local hormone produced by some cells that initiates growth.

GROWTH HORMONE. A hormone that eventually stimulates growth. Also called somatotropin.

GROWTH PLATE. The place in long bones where growth occurs during childhood.

GUAIAC. A compound derived from the wood resin of guaiacum trees. Guaiac reacts with blood in the stool to produce a blue-colored reaction when peroxide is added to the sample.

GUAIAC SMEAR TESTING. Guaiac fecal occult blood testing; a screening test for hidden (occult) blood in the stool.

GUIDE WIRE. A wire that is inserted into an artery to guide a catheter to a certain location in the body.

GUIDED IMAGERY. The use of relaxation and mental visualization to improve mood and/or physical well-being.

GUILLAIN-BARRÉ SYNDROME (GBS). A disease of the nerves with symptoms that include sudden numbness and weakness in the arms and legs, sometimes leading to paralysis. The disease is serious and requires medical treatment, but most people recover completely.

GUINEA WORM EMBRYO. The guinea worm at its earliest life stage prior to or shortly after being expelled from an adult female worm.

GUINEA WORM LARVAE. The guinea worm during its middle life stage as it matures within a water flea. The larvae can only grow to adulthood within a human host.

GUMMA. A rubbery swelling or tumor that heals slowly and leaves a scar and is a symptom of tertiary syphilis.

GUTTA PERCHA. An inert, latex-like substance used for filling root canals.

GYNECOLOGIC SURGERY. Gynecologic procedures include surgeries on the female reproductive system.

GYNECOLOGIST. A physician with specialized training in diseases and conditions of the female reproductive system.

GYNECOMASTIA. Overly developed or enlarged breasts in a male.

H

H_2 ANTAGONIST. A type of drug that relieves indigestion by reducing the production of stomach acid.

H2 BLOCKERS. Medications used to treat some GERD symptoms, for example, Tagamet, Pepcid, and Axid.

HABIT. Referring to the particular set of physical and mental tensions present in any individual.

HAIR CELLS. Sensory receptors in the inner ear that transform sound vibrations into messages that travel to the brain.

HAIR FOLLICLE. A tube-like indentation in the skin from which a single hair grows.

HAIRBULB. The root of a strand of hair from which the color develops.

HALF-LIFE. The time required for half of the atoms in a radioactive substance to disintegrate.

HALITOSIS. The medical term for bad breath.

HALLUCINATION. A false or distorted perception of objects, sounds, or events that seems real. Hallucinations usually result from drugs or mental disorders.

HALLUCINOGEN. Substance that causes distorted perceptions and/or unreal dreams.

HALLUCINOGEN PERSISTING PERCEPTION DISORDER (HPPD). The recurrence of LSD effects after the drug experience has ended.

HANTAVIRUS. A group of arboviruses that cause hemorrhagic fever (characterized by sudden onset, fever, aching, and bleeding in the internal organs).

HAPTOGLOBIN. A blood protein made by the liver. Its main role is to save iron by attaching itself to any hemoglobin released from a red cell.

HARVESTING. The process of removing tissues or organs from a donor and preserving them for transplantation.

HASHIMOTO'S DISEASE. An autoimmune disorder that is the most common cause of primary hypothyroidism. It was the first disease to be recognized as an autoimmune disorder. It is named for a Japanese doctor, Hakaru Hashimoto, who first described it in 1912.

HATHA YOGA. Form of yoga using postures, breathing methods, and meditation.

HDL CHOLESTEROL. About one-third or one-fourth of all cholesterol is high-density lipoprotein cholesterol. High levels of HDL, nicknamed "good" cholesterol, decrease the risk of atherosclerosis.

HEAD-UPRIGHT TILT TABLE TEST. A test used to determine the cause of fainting spells. During the test, the patient is tilted at different angles on a special table for a period of time. During the test, the patient's heart rhythm, blood pressure, and other measurements are evaluated with changes in position.

HEART ATTACK. A cardiac emergency that occurs when a clot blocks blood flow in one or more of the heart's arteries. Oxygen supply to the heart muscle is cut off, resulting in the death of heart tissue in the affected area.

HEART BLOCK. A problem with electrical conduction in the heart muscle that may lead to irregular heartbeat and require a pacemaker for treatment.

HEART CATHETERIZATION. A heart catheterization is used to view the heart's chamber and valves. A tube

WWW.BOOKBAZ.IR

(catheter) is inserted into an artery, usually in the groin. A dye is then put into the artery through the tube. The dye makes its way to the heart to create an image of the heart on x-ray film. The image is photographed and stored for further examination.

HEART FAILURE. A term used when the heart is unable to pump enough blood to supply the needs of the body.

HEART MURMUR. Sound during the heartbeat caused by a heart valve that does not close properly.

HEART VALVES. Valves that regulate blood flow into and out of the heart chambers.

HEARTBURN. A sensation of warmth or burning behind the breastbone, rising upward toward the neck. It is often caused by stomach acid flowing upward from the stomach into the esophagus.

HEARTWORM DISEASE. A parasitic disease that affects dogs, cats, and ferrets, spread by mosquitoes from one infected pet to another. The larvae migrate to the arteries supplying the heart and lungs of infected animals, where they mature and reproduce.

HEAT STROKE. A serious condition that results from exposure to extreme heat. The body loses its ability to cool itself. Severe headache, high fever, and hot, dry skin may result. In severe cases, a person with heat stroke may collapse or go into a coma.

HEAVY METAL. One of 23 chemical elements that has a specific gravity (a measure of density) at least five times that of water.

HEIMLICH MANEUVER. An emergency procedure for removing a foreign object lodged in the airway that is preventing the person from breathing.

HELICOBACTER PYLORI. A gram-negative rod-shaped bacterium that lives in the tissues of the stomach and causes inflammation of the stomach lining.

HELMINTH. A type of parasitic worm. Threadworms belong to a subcategory of helminths called nematodes, or roundworms.

HEMAGGLUTINATION. The clumping or clustering of red blood cells caused by certain viruses, antibodies, or other substances.

HEMARTHROSIS. A condition of blood within a joint.

HEMATIN. A drug administered intravenously to halt an acute porphyria attack. It causes heme biosynthesis to decrease, preventing the further accumulation of heme precursors.

HEMATOCRIT. The separation of red blood cells from plasma to determine their percent volume in whole blood.

HEMATOCRIT (HCT) LEVEL. A measure of red blood cells.

HEMATOLOGIST. A doctor who specializes in studying and treating diseases of the blood.

HEMATOLOGY. The medical specialty that deals with the blood and the organs that form blood.

HEMATOMA. A localized collection of blood in an organ or tissue due to broken blood vessels.

HEMATOPOIETIC CELLS. Those cells that are lodged within the bone marrow and are responsible for producing the cells that circulate in the blood (red blood cells, white blood cells, and platelets).

HEMATOPOIETIC STEM CELL. A cell that can develop into any type of specialized blood cell.

HEMATOPOIETIC SYSTEM. The system in the body which is responsible for the production of blood cells.

HEMATOPORPHYRIN. A dark reddish-purple pigment found in blood. A purified form of hematoporphyrin is used to make porfimer sodium.

HEMATURIA. Blood in the urine.

HEME. The iron-containing pigment found in hemoglobin.

HEMIPLEGIA. Paralysis of one side of the body.

HEMISPHERE. One of the two halves or sides—the left and the right—of the brain.

HEMIVERTEBRA. Condition in which one side of a vertebra fails to form normally before birth.

HEMOCHROMATOSIS. A disorder of iron metabolism characterized by excessive absorption of iron from food.

HEMOCYTOMETER. An instrument used to count platelets or other blood cells.

HEMODIALYSIS. A method of mechanically cleansing the blood outside of the body, in order to remove various substances that would normally be cleared by the kidneys. Hemodialysis is used when an individual is in relative, or complete, kidney failure.

HEMODILUTION. A technique in which the fluid content of the blood is increased without increasing the number of red blood cells.

HEMOGLOBIN. A chemical found in red blood cells that transports oxygen.

HEMOGLOBIN A. Normal adult hemoglobin that contains four heme molecules, two alpha-globin molecules, and two beta-globin molecules.

HEMOGLOBIN C DISEASE. A disease of abnormal hemoglobin, occurring in 2–3% of African Americans. Only those who have two genes for the disease develop anemia, which varies in severity. Symptoms include episodes of abdominal and joint pain, an enlarged spleen and mild jaundice.

HEMOGLOBIN ELECTROPHORESIS. A laboratory test that separates molecules based on their size, shape, or electrical charge.

HEMOGLOBIN H DISEASE. A thalassemia-like syndrome causing moderate anemia and red blood cell abnormalities.

HEMOGLOBIN S. Hemoglobin produced in association with the sickle cell trait; the beta-globin molecules of hemoglobin S are defective.

HEMOLYSIS. The process of breaking down red blood cells. As the cells are destroyed, hemoglobin, the component of red blood cells which carries the oxygen, is liberated.

HEMOLYTIC. Able to break down or dissolve red blood cells. The bacteria that cause lymphadenitis are hemolytic.

HEMOLYTIC ANEMIA. A type of anemia marked by the breakdown of red blood cells causing the release of hemoglobin.

HEMOLYTIC BACTERIA. Bacteria that are able to burst red blood cells.

HEMOLYTIC UREMIC SYNDROME (HUS). A potentially fatal complication of *E. coli* infections characterized by kidney failure and destruction of red blood cells.

HEMOPHILIA. An inherited bleeding disorder caused by a deficiency of factor VIII, one of a series of blood proteins essential for blood clotting.

HEMOPTYSIS. Spitting up blood from the lungs or sputum stained with blood.

HEMORRHAGE. Heavy bleeding.

HEMORRHAGIC. A condition resulting in massive, difficult-to-control bleeding.

HEMORRHAGIC STROKE. A stroke caused by a burst blood vessel in the brain.

HEMORRHOID. An area around the anus where veins become dilated and the tissue swells, causing itching and pain.

HEMOSIDEROSIS. An overload of iron in the body resulting from repeated blood transfusions. Hemosiderosis occurs most often in patients with thalassemia.

HEMOSTASIS. Slowing down or stopping bleeding.

HEMOSTATIC. Relating to blood clotting and coagulation.

HEMOTHORAX. Blood in the pleural cavity.

HENDRA. A virus related to the nipah virus that infected horses and humans in Australia in 1994.

HENNA. Mehndi; a reddish-brown dye from the leaves of the henna plant; used for hair dye and temporary tattoos.

HENIPAVIRUS. A genus of viruses in the Paramyxoviridae family that thus far only includes the nipah and hendra viruses.

HEPARIN. A blood component that controls the amount of clotting. It can be used as a drug to reduce blood clot formation.

HEPARIN CHALLENGE TEST. A medical test to evaluate how readily the blood clots.

HEPATIC. Of the liver, from the Greek word *hepar*.

HEPATIC ARTERY. The blood vessel supplying arterial blood to the liver.

HEPATITIS. Inflammation of the liver, caused by infectious or toxic agents and characterized by jaundice, fever, liver enlargement, and abdominal pain.

HEPATITIS B. A disease that causes inflammation of the liver and serious liver damage.

HEPATITIS B AND C. Viruses that can damage the liver and may be vertically transmitted during childbirth.

HEPATOBILIARY SCAN. Another term for a gallbladder nuclear medicine scan.

HEPATOCELLULAR. Of or pertaining to liver cells.

HEPATOCYTE. A liver cell.

HEPATOMEGALY. General swelling of the liver.

HEPATOTOXIN. A substance that is toxic to the liver.

HER2. Human epidermal growth factor receptor 2, which is overproduced in HER2-positive breast cancers.

WWW.BOOKBAZ.IR

HERB. In naturopathy, a plant or plant derivative or extract prescribed for health or healing.

HERBIVORE. An animal whose diet consists primarily or entirely of plant matter. Herbivorous animals include deer, sheep, cows, horses, elephants, giraffes, and bison.

HERD IMMUNITY. Community immunity; disease protection for non-immune or unvaccinated individuals that is conferred by the prevailing immunity within a population due to widespread vaccination coverage.

HEREDITARY. Something that is inherited or passed down from parents to offspring. In biology and medicine, the word pertains to inherited genetic characteristics.

HEREDITARY ANGIOEDEMA. A complement deficiency characterized by lymphatic vessel blockages that cause temporary swelling (edema) of areas of the skin, mucous membranes, and, sometimes, internal organs.

HEREDITARY ATAXIA. One of a group of hereditary degenerative diseases of the spinal cord or cerebellum. These diseases cause tremor, spasm, and wasting of muscle.

HEREDITARY NON-POLYPOSIS COLORECTAL CANCER; HNPCC. Lynch syndrome; inherited colorectal cancer that is not characterized by the development of polyps.

HEREDITARY SPHEROCYTOSIS. A hereditary disorder that leads to a chronic form of anemia (too few red blood cells) due to an abnormality in the red blood cell membrane.

HERMANSKY-PUDLAK SYNDROME (HPS). A rare type of albinism characterized by a problem with blood clotting and a buildup of waxy material in lungs and intestines.

HERNIA. The protrusion of a loop or section of an organ or tissue through an abnormal opening.

HERNIATE. To protrude beyond usual limits.

HERNIATED DISK. A blister-like bulging or protrusion of the contents of an intervertebral disk; also called a prolapsed, slipped, displaced, or ruptured disk.

HERNIORRHAPHY. Surgical repair of a hernia.

HEROIN. An illegal and highly addictive narcotic that is made from morphine and is widely abused for its euphoric effects.

HERPES. A family of viruses including herpes simplex types 1 and 2, and herpes zoster (also called varicella zoster). Herpes viruses cause several infections, all characterized by blisters and ulcers, including chickenpox, shingles, genital herpes, and cold sores or fever blisters.

HERPES SIMPLEX VIRUS. A virus that can cause fever and blistering on the skin, mucous membranes, or genitalia.

HERPES ZOSTER VIRUS. Acute inflammatory virus that attacks the nerve cells on the root of each spinal nerve with skin eruptions along a sensory nerve ending.

HERTZ (HZ). A unit of frequency; 1 Hz is equal to one cycle per second.

HETEROTOPIC BONE. Bone that develops as an excess growth around the hip joint following surgery.

HETEROTROPHIC TRANSPLANTATION. The addition of a donor liver at another site, while the diseased liver is left intact.

HETEROZYGOTE. An individual who has one gene in a pair that has a mutation while the other gene in the pair is unaffected.

HETEROZYGOUS. Two different genes controlling a specified inherited trait.

HIATAL HERNIA. A condition in which part of the stomach protrudes above the diaphragm next to the esophagus.

HIGH SPOT. An area of a tooth or restoration that feels abnormal or uncomfortable because it hits its opposing tooth before other teeth meet.

HIGH-FUNCTIONING AUTISM (HFA). A subcategory of autistic disorder consisting of children diagnosed with IQs of 70 or higher.

HIGHLY ACTIVE ANTIRETROVIRAL THERAPY (HAART). An individualized combination or drug cocktail of three or more antiretroviral drugs for treating HIV/AIDS.

HIGH-RISK HPV TYPE. A member of the HPV family of viruses that is associated with the development of cervical cancer and precancerous growths.

HIPPOCAMPUS. A part of the brain's limbic system that is involved in memory formation and learning.

HIRSCHSPRUNG DISEASE. Hirschsprung disease is a congenital abnormality (birth defect) of the bowel in which there is absence of the ganglia (nerves) in the wall of the bowel. Nerves are missing starting at the

anus and extending a variable distance up the bowel. This results in megacolon (massive enlargement of the bowel) above the point where the nerves are missing. (The nerves are needed to assist in the natural movement of the muscles in the lining of the bowels that move bowel contents through.)

HIRSUTISM. An abnormal growth of hair on the face and other parts of the body caused by an excess of androgens.

HISTAMINE. A chemical released by mast cells that activates pain receptors and causes cells to become leaky.

HISTOCOMPATIBILITY ANTIGENS. Proteins scattered throughout body tissues that are unique for almost every individual.

HISTOCOMPATIBILITY TESTING. Testing of genotypes of a recipient and potential donor to see whether rejection would occur when tissues are transplanted.

HISTOLOGY. The study of the structure, composition, and function of tissues of organs.

HISTOPATHOLOGY. The study of diseased tissues at a microscopic level.

HISTRIONIC. Relating to being very dramatic or excessive in behavior.

HIV. Acronym for human immunodeficiency virus, the virus that causes AIDS.

HIV/AIDS. Human immunodeficiency virus/acquired immunodeficiency syndrome.

HIV/AIDS. Human immunodeficiency virus/acquired immunodeficiency syndrome.

HIVES. Urticaria; itchy bumps on the skin from an allergic reaction.

HLA-B27. An antigen or protein marker on cells that may indicate ankylosing spondylitis.

HODGKIN'S DISEASE. A type of cancer involving the lymph nodes and potentially affecting non-lymphatic organs in the later stage.

HOLISTIC. A practice of medicine that focuses on the whole patient, and addresses the social, emotional, and spiritual needs of a patient as well as their physical treatment.

HOLTER MONITOR. A small machine, worn by a patient usually for 24 hours, that continuously records the patient's EKG during usual daily activity.

HOME HEALTH AIDE. An employee of a home care agency who provides the same services to a patient in the home as nurses' aides perform in hospitals and nursing homes.

HOME MODIFICATION. The altering of the physical environment of the home to remove hazards and provide a more functional environment; examples include the installation of grab bars and no-slip foot mats in the bathroom to prevent falls.

HOME PARENTERAL NUTRITION (HPN). Long-term parenteral nutrition, given through a central venous catheter and administered in the patient's home.

HOMEOPATHIC. A holistic and natural approach to healthcare.

HOMEOPATHY. A system of alternative medicine that arose in Germany in the late eighteenth century that emphasizes treating the symptoms of a given disease with highly dilute remedies made from substances that cause the symptoms of the disease in healthy people.

HOMEOSTASIS. The tendency of a family system to maintain internal stability and resist change.

HOMOCYSTEINE. An amino acid normally found in small amounts in the blood.

HOMOZYGOTE. An individual who has both genes in a pair with the same mutation.

HOMOZYGOUS. Identical genes controlling a specified inherited trait.

HOOK-UP. A state of effortless connection with a life-enhancing force. Trager practitioners enter a state of hook-up before working with clients in order to focus on their needs. Trager himself described hook-up as a meditative process of "becoming one with the energy force that surrounds all living things."

HOOKWORM. Parasitic intestinal infestation caused by any of several parasitic nematode worms of the family Ancylostomatidae. These worms have strong buccal hooks that attach to the host's intestinal lining.

HORMONAL THERAPY. Use of hormone medications to inhibit menstruation and relieve the symptoms of endometriosis.

HORMONE. A chemical messenger that is produced by one type of cell and travels through the bloodstream to change the metabolism of a different type of cell.

HORMONE REPLACEMENT THERAPY (HRT). The use of estrogen and progesterone to replace hormones that the ovary no longer supplies. HRT is no longer used as long-term therapy for postmenopausal women.

WWW.BOOKBAZ.IR

HORMONE THERAPY. Treatment of cancer by inhibiting the production of hormones such as testosterone and estrogen.

HORMONE THERAPY. Treatment of cancer by inhibiting the production of hormones such as testosterone and estrogen.

HOSPICE. An approach for providing compassionate, palliative care to terminally ill patients and counseling or assistance for their families. The term may also refer to a hospital unit or freestanding facility devoted to the care of terminally ill patients.

HOST. The organism (such as a monkey or human) in which another organism (such as a virus or bacteria) is living.

HOT FLASH. A wave of heat that is one of the most common perimenopausal symptoms, triggered by the hypothalamus' response to estrogen withdrawal.

HOT TUB FOLLICULITIS. A skin infection caused by *Pseudomonas aeruginosa* that often follows bathing in a hot tub or public swimming pool.

HUMAN CHORIONIC GONADOTROPIN (HCG). A hormone produced by the placenta during pregnancy.

HUMAN HERPESVIRUS 8. Also called Kaposi's sarco-associated herpesvirus (KSHV), this virus is thought to be a cause for KS.

HUMAN IMMUNODEFICIENCY VIRUS (HIV). The virus that causes acquired immune deficiency syndrome (AIDS).

HUMAN IMMUNODEFICIENCY VIRUS GROUPS. HIV classification has evolved into several groups, allowing for further distinction; specific lineages are now termed as groups M, N, O, and P. M is considered the pandemic strain and comprises the vast majority of strains of HIV. Viruses from the M group are then divided into subtypes, of which there are 10 identified currently (A to J). Subtypes are also known as clades. The most common clade in the United States and Europe is HIV clade B; HIV testing was originally developed to identify HIV clade B.

HUMAN LEUKOCYTE ANTIGEN (HLA). A group of protein molecules located on bone marrow cells that can provoke an immune response. A donor's and a recipient's HLA types should match as closely as possible to prevent the recipient's immune system from attacking the donor's marrow as a foreign material that does not belong in the body.

HUMAN PAPILLOMAVIRUS (HPV). A group of viruses that cause abnormal cell growth (warts or papillomas); some types can cause cervical cancer.

HUMAN POTENTIAL MOVEMENT. A movement in psychotherapy that began in the 1960s and emphasized maximizing the potential of each participant through such techniques as group therapy and sensitivity training.

HUMANIZE. Fusing the constant and variable framework region of one or more human immunoglobulins with the binding region of an animal immunoglobulin, done to reduce human reaction against the fusion antibody.

HUMERUS. The long bone of the upper arm that runs from the shoulder blade to the elbow joint.

HUMORAL. Pertaining to or derived from a body fluid. The humoral part of the immune system includes antibodies and immunoglobulins in blood serum.

HUNTINGTON DISEASE. The long bone of the upper arm that runs from the shoulder blade to the elbow joint.

HYALINE MEMBRANE. A thin layer of cells that line the lung.

HYDATIDIFORM MOLE. Also called a molar pregnancy. A mass of abnormal, partially developed tissues inside the uterus (womb). Moles develop during a pregnancy that begins with an abnormal fertilization. The mass may or may not be cancerous.

HYDROCELE. Collection of fluid in the scrotum.

HYDROCEPHALUS. Swelling of the brain caused by an accumulation of fluid.

HYDROCOLLOID. Dressing material that turns into a gel when combined with watery drainage.

HYDROCORTISONE. A steroid hormone produced by the adrenal glands that provides resistance to stress.

HYDROGEL. A water-based dressing material.

HYDROGEN. The simplest, most common element known in the universe. It is composed of a single electron (negatively charged particle) circling a nucleus consisting of a single proton (positively charged particle). It is the nuclear proton of hydrogen that makes MRI possible by reacting resonantly to radio waves while aligned in a magnetic field.

HYDRONEPHROSIS. Severe swelling of the kidney due to backup of urine. It may occur because of an obstruction, calculi, tumor, or other pathological conditions.

HYDROPHILIC. Dressing material that absorbs water.

HYDROPS FETALIS. A condition in which a fetus or newborn baby accumulates fluids, causing swollen arms and legs and impaired breathing.

HYDROSALPINX. A condition in which a fallopian tube becomes blocked and filled with fluid.

HYDROTHERAPY. Hydrotherapy, or water therapy, is use of water (hot, cold, steam, or ice) to relieve discomfort and promote physical well-being.

HYDROXYAPATITE. A calcium phosphate complex that is the primary mineral component of bone.

HYDROXYUREA. A drug that has been shown to induce production of fetal hemoglobin. Fetal hemoglobin has a pair of gamma-globin molecules in place of the typical beta-globins of adult hemoglobin. Higher-than-normal levels of fetal hemoglobin can prevent sickling from occurring.

HYMEN. A membrane that partially or completely covers the vaginal opening.

HYMENOLEPIASIS. Parasitic infection caused by the presence of tapeworms from the *Hymenolepis* genus, such as the dwarf tapeworm (*Hymenolepis nana*) or the rodent tapeworm (*Hymenolepis diminuta*).

HYPERANDROGENISM. Excessive secretion of androgens (male sex hormones).

HYPERAROUSAL. A state or condition of muscular and emotional tension produced by hormones released during the fight-or-flight response to a stimuli.

HYPERBARIC CHAMBER. A sealed compartment in which air pressure is gradually increased and then gradually decreased, allowing nitrogen bubbles to shrink and the nitrogen to safely diffuse out of body tissue.

HYPERBARIC OXYGEN THERAPY. Pure oxygen is administered to the patient in a special chamber at three times the normal atmospheric pressure. The patient gets more oxygen faster to overcome severe asphyxiation.

HYPERBARIC OXYGENATION. Pure oxygen is administered to the patient in a special chamber at three times the normal atmospheric pressure. The patient gets more oxygen faster to overcome severe asphyxiation.

HYPERBILIRUBINEMIA. A condition in which bilirubin accumulates to abnormally high levels in the bloodstream.

HYPERCALCEMIA. Abnormally high levels of calcium in the blood.

HYPERCOAGULATION. Excessive clotting of the blood.

HYPEREMESIS. Severe vomiting during pregnancy. Hyperemesis appears to increase a woman's risk of postpartum depression.

HYPEREMESIS GRAVIDARUM. The medical term for intractable nausea and vomiting associated with pregnancy. It affects about 0.5% of pregnant women.

HYPEREXTENSIBILITY. The ability to extend a joint beyond the normal range.

HYPERGLYCEMIA. Condition characterized by excessively high levels of glucose in the blood, and occurs when the body does not have enough insulin or cannot use the insulin it does have to turn glucose into energy. Hyperglycemia is often indicative of diabetes that is out of control.

HYPERHIDROSIS. Excessive sweating. Hyperhidrosis can be caused by heat, overactive thyroid glands, strong emotion, menopause, or infection.

HYPERINFECTION SYNDROME. A condition of massive infection in which threadworm larvae multiply rapidly and spread throughout the body. It is usually associated with damage to the immune system, the use of steroid medications, or malnutrition.

HYPERINSULINEMIA. The medical term for high levels of insulin in the blood.

HYPERKALEMIA. An abnormally high level of potassium in the blood.

HYPERKETONEMIA. Condition characterized by an overproduction of ketones by the body.

HYPERLACTATION. Another term for galactorrhea.

HYPERLIPIDEMIA. Abnormally high levels of lipids in the blood.

HYPERMAGNESEMIA. An abnormally high concentration of magnesium in the blood.

HYPERMOBILITY. Unusual flexibility of the joints, allowing them to be bent or moved beyond their normal range of motion.

HYPEROPIA. The inability to see near objects as clearly as distant objects, and the need for accommodation to see objects clearly.

HYPEROSMOTIC. Hypertonic, containing a higher concentration of salts or other dissolved materials than normal tissues.

WWW.BOOKBAZ.IR

HYPEROSMOTIC DRUGS. Refers to a class of drugs for glaucoma that increase the osmotic pressure in the blood, which then pulls water from the eye into the blood.

HYPEROSTOSIS. Excessive growth of bone.

HYPERPARATHYROIDISM. Overactivity of the parathyroid glands. Symptoms include generalized aches and pains, depression, and abdominal pain.

HYPERPHAGIA. Over-eating.

HYPERPIGMENTATION. A skin condition that occurs when the body has too much melanin, or pigment.

HYPERPLASIA. The abnormal increase in the number of normal cells in a given tissue.

HYPERPLASTIC. Overgrown.

HYPERPLASTIC OBESITY. Excessive weight gain in childhood, characterized by an increase in the number of fat cells.

HYPERSECRETORY. Excessive secretions, overproduction of stomach acid.

HYPERSENSITIVITY. The state where even a tiny amount of allergen can cause severe allergic reactions.

HYPERSOMNIA. Excessive and reoccurring daytime sleepiness.

HYPERTENSION. Persistently high arterial blood pressure.

HYPERTENSIVE HEART DISEASE. High blood pressure resulting in a disease of the heart.

HYPERTHERMIA. Elevated body temperature, as from heatstroke.

HYPERTHERMIA THERAPY. A type of treatment in which body tissue is exposed to high temperatures to damage and kill cancer cells or to make cancer cells more sensitive to the effects of radiation and certain anticancer drugs.

HYPERTHYROID. Having too much thyroxin stimulation.

HYPERTHYROIDISM. Secretion of excess thyroid hormones by the thyroid gland.

HYPERTONIA. Having excessive muscular tone.

HYPERTROPHIC. Enlarged.

HYPERTROPHIC OBESITY. Excessive weight gain in adulthood, characterized by expansion of pre-existing fat cells.

HYPERTROPHY. The overgrowth of muscle or tissue.

HYPERURICEMIA. High uric acid levels in the blood.

HYPERVENTILATION. A respiratory therapy involving deeper and/or faster breathing to keep the carbon dioxide pressure in the blood below normal.

HYPERVIGILANCE. A state of abnormally intense wariness or watchfulness that is found in survivors of trauma or long-term abuse. Hypervigilance is sometimes described as the feeling of being on red alert all the time.

HYPERVISCOSITY. Thick, viscous blood, caused by the accumulation of large proteins, such as immunoglobulins, in the serum.

HYPERVITAMINOSIS. Another name for vitamin toxicity.

HYPNOGOGIC HALLUCINATION. Dream-like auditory or visual hallucinations that occur while falling asleep.

HYPNOPOMPIC HALLUCINATION. A hallucination that occurs as a person is waking from sleep.

HYPNOSIS. The means by which a state of extreme relaxation and suggestibility is induced: used to treat amnesia and identity disturbances that occur in dissociative disorders.

HYPNOTIC. A medicine that causes sleep.

HYPNOTIC AGENT. A drug capable of inducing an altered state of consciousness.

HYPNOTIC STATE. A state of heightened focus and concentration with an increased susceptibility to suggestion, trance-like.

HYPOALBUMINEMIA. An abnormally low level of albumin in the blood plasma.

HYPOCALCEMIA. An abnormally low level of calcium in the blood.

HYPOCHROMIC. A descriptive term applied to a red blood cell with a decreased concentration of hemoglobin.

HYPODERMOCLYSIS. A technique for restoring the body's fluid balance by injecting a solution of salt and water into the tissues beneath the skin rather than directly into a vein.

HYPOGLYCEMIA. Abnormally low levels of glucose in the blood.

HYPOGONADISM. Functional incompetence of the male gonads, with impaired production of hormones and germ cells.

HYPOKALEMIA. A deficiency of potassium in the blood.

HYPOMAGNESEMIA. An abnormally low concentration of magnesium in the blood.

HYPOMANIA. A less severe form of elevated mood state that is a characteristic of bipolar type II disorder.

HYPONATREMIA. A deficiency of sodium in the blood.

HYPOPARATHYROIDISM. Insufficient production of parathyroid hormone, which results in low levels of blood calcium.

HYPOPIGMENTATION. Decreased pigmentation or color on a portion of the skin.

HYPOPITUITARISM. Underactivity of the pituitary gland.

HYPOPLASIA. A deficiency or underdevelopment of a tissue or body structure.

HYPOPLASTIC. Incomplete or underdevelopment of a tissue or organ. Hypoplastic left heart syndrome is the most serious type of congenital heart disease.

HYPOPLASTIC ANEMIA. Anemia that is characterized by defective function of the blood-forming organs (such as bone marrow) and is caused by toxic agents such as chemicals or x rays. Anemia is a blood condition in which there are too few red blood cells or the red blood cells are deficient in hemoglobin.

HYPOPNEA. Shallow or excessively slow breathing usually caused by partial closure of the upper airway during sleep, leading to disruption of sleep.

HYPOPYON. A small amount of pus or collection of white cells that is visible in the front of the eye in severe cases of anterior uveitis.

HYPOSPADIAS. A congenital deformity of the penis where the urinary tract opening is not at the tip of the glans.

HYPOTENSION. Low blood pressure.

HYPOTHALAMIC-PITUITARY-GONADAL (HPG) AXIS. A term used by doctors to refer to the combined effects of the hypothalamus, the pituitary gland, and the gonads. This group of glands controls sexual maturation in humans as well as other processes.

HYPOTHALAMUS. A structure within the brain responsible for a large number of normal functions throughout the body, including regulating sleep, temperature, eating, and sexual development. The hypothalamus also regulates the functions of the pituitary gland by directing the pituitary to stop or start production of its hormones.

HYPOTHERMIA. Low body temperature.

HYPOTHYROID. Having too little thyroxin stimulation.

HYPOTHYROIDISM. A disease condition in which the thyroid gland does not produce enough thyroid hormone.

HYPOTONIA. Reduced or diminished muscle tone.

HYPOVENTILATION. Reduced ventilation in the lungs' air sacs resulting in above normal carbon dioxide pressure.

HYPOVOLEMIA. A decrease in the volume of blood plasma.

HYPOVOLEMIC. Having a low volume.

HYPOVOLEMIC SHOCK. Shock caused by a lack of circulating blood.

HYPOXEMIA. Insufficient oxygenation of the blood.

HYPOXIA. The medical term for deprivation of an adequate oxygen supply, either to specific tissues or to the entire organism.

HYSTERECTOMY. Surgical removal of the uterus.

HYSTERIA. The earliest term for a psychoneurotic disturbance marked by emotional outbursts and/or disturbances of movement and sense perception. Some forms of hysteria are now classified as somatoform disorders and others are grouped with the dissociative disorders.

HYSTERICAL NEUROSIS. An older term for conversion disorder or dissociative disorder.

HYSTEROSALPINGOGRAPHY (HSG). X raying of the uterus and fallopian tubes following the injection of a contrast dye.

HYSTEROSCOPY. A procedure in which an endoscope is inserted through the cervix to view the cervix and uterus.

HYSTEROTOMY. A surgical incision of the uterus.

WWW.BOOKBAZ.IR

I

I & D. Incision and drainage of a wound.

IATROGENIC. Resulting from the activity of the physician.

IATROGENIC KAPOSI'S SARCOMA. A form of KS that develops in transplant patients who take immunosuppressive drugs to prevent rejection of their organ transplant.

ICHTHYOSIS. A group of congenital disorders of keratinization characterized by dryness and scaling of the skin.

ICTAL EEG. Used to measure brain activity during a seizure. May be useful in learning more about patients who aren't responding to conventional treatments.

ICTERUS. Jaundice.

IDEAL WEIGHT. Weight corresponding to the lowest death rate for individuals of a specific height, gender, and age.

IDEATION. The formulating or entertaining of ideas, such as the idea of committing suicide.

IDENTIFICATION WITH AN AGGRESSOR. In psychology, an unconscious process in which a person adopts the perspective or behavior patterns of a captor or abuser. Some researchers consider it a partial explanation of Stockholm syndrome.

IDENTIFIED PATIENT (IP). The family member in whom the family's symptom has emerged or is most obvious.

IDIOPATHIC. Of unknown origin; without a known cause.

IDIOPATHIC CARDIOMYOPATHY. Cardiomyopathy without a known cause.

IDIOPATHIC THROMBOCYTOPENIA PURPURA (ITP). A rare autoimmune disorder characterized by an acute shortage of platelets with resultant bruising and spontaneous bleeding.

IDIOSYNCRASY. A defect in that particular pathway resulting in an abnormality.

ILEUM. The lowest part of the small intestine, located beyond the duodenum and jejunum, just before the large intestine (the colon).

ILEUS. Obstruction of the intestines caused by the absence of peristalsis.

ILIAC ARTERY. Large blood vessel in the pelvis that leads into the leg.

ILIZAROV FRAME. A device invented by a Russian physician for correcting deformities of the legs and feet, consisting of rings to be attached to the bone and rods extending between the rings that stretch the affected limb.

ILLUSION. A false visual perception of an object that others perceive correctly. A common example is the number of sightings of "UFOs" that turn out to be airplanes or weather balloons.

IMIQUIMOD. A drug, approved by the FDA to treat warts, that may destroy basal cell carcinomas by stimulating the immune system. Also known by its trade name Aldara.

IMMEDIATE HYPERSENSITIVITY REACTIONS. Allergic reactions that are mediated by mast cells and occur within minutes of allergen contact.

IMMUNE COMPLEXES. Clusters or aggregates of antigen and antibody bound together.

IMMUNE FUNCTION. The state in which the body recognizes foreign materials and is able to neutralize them before they can do any harm.

IMMUNE GLOBULIN. Serum containing antibodies against a specific infection.

IMMUNE RESPONSE. Physiological response of the body controlled by the immune system that involves the production of antibodies to fight off specific foreign substances or agents (antigens).

IMMUNE SUPPRESSANT DRUG. Any drug that dampens immune responses and decreases inflammation.

IMMUNE SUPPRESSING. Anything that reduces the activity of the immune system.

IMMUNE SYSTEM. The body's natural defenses against disease and infection.

IMMUNIZATION. Administering a vaccine that stimulates the body to create antibodies to a specific disease (immunity) without causing symptoms of the disease.

IMMUNOASSAY. A biochemical test that measures the presence of a substance in a body fluid sample through the use of an immunoglobulin or an antibody.

IMMUNOCOMPETENCE. An individual's ability to fight off infection.

IMMUNOCOMPROMISED. A state in which the immune system is suppressed or not functioning properly.

IMMUNODEFICIENCY. A disorder in which the immune system is ineffective or disabled due either to acquired or inherited disease.

IMMUNOELECTROPHORESIS. Use of an electrical field to separate proteins in a mixture (such as blood or urine), on the basis of the size and electrical charge of the proteins; followed by the detection of an antigen (such as IgM), using a specific antibody.

IMMUNOFLUORESCENCE ASSAY (IFA). A blood test sometimes used to confirm ELISA results instead of using the Western blotting. In an IFA test, HIV antigen is mixed with a fluorescent compound and then with a sample of the patient's blood. If HIV antibody is present, the mixture will fluoresce when examined under ultraviolet light.

IMMUNOGLOBULIN (IG). A substance made by B cells that neutralizes specific disease-causing substances and organisms. Also called "antibody." Immunoglobulins are divided into five classes: IgA, IgD, IgE, IgG, and IgM.

IMMUNOGLOBULIN E (IGE). Antibodies produced in the lungs, skin, and mucous membranes that are responsible for allergic reactions.

IMMUNOGLOBULIN G (IGG). A group of antibodies against certain viral infections that circulate in the bloodstream. One type of IgG is specific against the mumps paramyxovirus.

IMMUNOGLOBULIN M (IGM). A type of antibody that is produced early in an infection.

IMMUNOLOGY. The branch of medicine that focuses on the body's immune system.

IMMUNOSUPPRESIVE CYTOTOXIC DRUGS. A class of drugs that function by destroying cells and suppressing the immune response.

IMMUNOSUPPRESSANT. Any agent that decreases the immune response of an individual.

IMMUNOSUPPRESSED. Any agent that decreases the immune response of an individual.

IMMUNOSUPPRESSION. A disorder or condition where the immune response is reduced or absent.

IMMUNOSUPPRESSIVE. Any agent that decreases the immune response of an individual.

IMMUNOSUPPRESSIVE DRUGS. Medications that suppress the immune system to prevent rejection of a transplant.

IMMUNOSUPPRESSIVE MEDICATION. Drugs given to a transplant recipient to prevent his or her immune system from attacking the transplanted organ.

IMMUNOSUPPRESSIVE THERAPY. Treatment that suppresses the immune system's functioning.

IMMUNOTHERAPY. Therapy that stimulates, enhances, or suppresses the body's immune response; includes products such as monoclonal antibodies, vaccines, and growth factors.

IMPACTED TOOTH. A tooth that is growing against another tooth, bone, or soft tissue.

IMPACTION. A condition in which earwax has become tightly packed in the outer ear to the point that the external ear canal is blocked.

IMPERFORATE ANUS. A congenital malformation (a birth defect) in which the rectum is a blind alley (a cul-de-sac) and there is no anus.

IMPLANT. A fixture with one end implanted into the bone and the other end covered with a crown, often to serve as a stable abutment for a bridge or denture.

IMPLANTABLE CARDIOVERTER-DEFIBRILLATOR (ICD). An electronic device that is surgically placed to constantly monitor the patient's heart rate and rhythm. If a very fast abnormal heart rate is detected, the device delivers electrical energy to the heart to beat in a normal rhythm again.

IMPLANTATION. The process in which the fertilized egg embeds itself in the wall of the uterus.

IMPOTENCE. The inability to achieve and sustain an erection suitable for intercourse.

IMPOTENT. The inability to achieve and sustain an erection suitable for intercourse.

IMPRESSION. An imprint of the upper or lower teeth made in a pliable material that sets. When this material has hardened, it may be filled with plaster, plastic, or artificial stone to make an exact model of the teeth.

IMPRINTING. Process that silences a gene or group of genes. The genes are silenced depending on if they are inherited through the egg or the sperm.

IN VITRO. A biological reaction occurring in a laboratory apparatus.

WWW.BOOKBAZ.IR

IN VIVO. A biological reaction occurring in a laboratory apparatus.

INCARCERATED HERNIA. A hernia that cannot be reduced, or pushed back into place inside the abdominal wall.

INCARCERATION. The abnormal confinement of a section of the intestine or other body tissues. An umbilical hernia may lead to incarceration of part of the intestine.

INCENTIVE SPIROMETER. A breathing device that provides feedback on performance to encourage deep breathing.

INCEST. Sexual intercourse between people who are too closely related to legally marry.

INCIDENCE. The rate of development of a disease in a given population over time.

INCISION. A cut, usually referring to the cut made by a surgeon during a surgical procedure.

INCISIONAL BIOPSY. Removal of a part of a lymph node for diagnostic purposes.

INCISORS. The eight front cutting teeth—four in the lower jaw and four in the upper jaw—located between the canines.

INCONTINENCE. The body's inability to control functions, usually urinary functions, or voiding or urine.

INCREASED INTRACRANIAL PRESSURE. A rise in the normal pressure levels inside the brain.

INCUBATION PERIOD. The time between exposure to an infectious agent, such as a virus or bacteria, and the appearance of symptoms of illness.

INCUS. The middle of the three bones of the middle ear. It is also known as the "anvil."

INDEX OF REFRACTION. A constant number for any material for any given color of light that is an indicator of the degree of the bending of the light caused by that material.

INDIA INK TEST. A diagnostic test used to detect the cryptococcal organism *C. neoformans*. A dye, called India ink, is added to a sample of CSF fluid, and if the fungi is present, they will become visible as the dye binds to the capsule surrounding the fungus.

INDIGESTION. A feeling of discomfort or illness that results from the inability to properly digest food.

INDIRECT TRAUMA. A term used to refer to symptoms of trauma in therapists, first responders, and others who treat trauma survivors. It is sometimes called *vicarious trauma*.

INDIUM. A silvery metallic element with some nonmetallic chemical properties used to label white blood cells prior to scanning.

INDOLENT LYMPHOMA (ALSO CALLED LOW-GRADE). Cancerous growths of lymphoid tissue that progress slowly to more aggressive forms of cancer.

INDURATION. An abnormally hard spot or area on the skin. The tuberculin skin test produces an induration at the test site in persons who have been exposed to TB.

INFANTICIDE. Intentional killing of a child within the first year of life.

INFANTILE SPASMS. Clusters of rapid jerks followed by stiffening or jackknife movements. Usually starts in the first year of life and stops by age 4.

INFARCTION. Death of tissue due to inadequate blood supply.

INFECTIOUS DISEASE. Any disease caused by invasion of a pathogen that subsequently grows and multiplies in the body.

INFECTIOUS DISEASE TEAM. A team of physicians who help control the hospital environment to protect patients against harmful sources of infection.

INFERIOR VENA CAVA. A large vein that returns blood from the legs, pelvis, and abdomen to the heart.

INFERTILITY. The inability of a man and woman to conceive a child after 12 months of unprotected sexual intercourse.

INFESTATION. A condition in which a parasite develops and multiplies on the body of its host rather than inside the body.

INFIBULATION. A procedure that closes the labia majora to prevent sexual intercourse, leaving only a small opening for the passage of urine and menstrual blood.

INFILTRATE. A tumor that moves into another organ of the body.

INFILTRATES. Cells or body fluids that have passed into a tissue or body cavity.

INFILTRATING LOBULAR CARCINOMA. A type of cancer that accounts for 8–10% of breast cancers. In breasts that are especially dense, ultrasound can be useful in identifying these masses.

INFLAMED BOWEL. Irritation of the intestinal tract.

INFLAMMATION. Pain, redness, swelling, and heat that usually develop in response to injury or illness.

INFLAMMATORY. Pain, redness, swelling, and heat that usually develop in response to injury or illness.

INFLAMMATORY BOWEL DISEASE (IBD). Disease in which the lining of the intestine becomes inflamed.

INFLAMMATORY RESPONSE. The immune system's response to tissue injury caused by a physical, chemical, or biological substance.

INFLUENZA. Commonly known as flu; an infectious disease of birds and mammals caused by viruses of the family Orthomyxoviridae (the influenza viruses); common symptoms of the disease are the chills, then fever, sore throat, muscle pains, severe headache, coughing, weakness and general feelings of illness.

INFORMED CONSENT. An educational process between healthcare providers and patients intended to instruct the patient about the nature and purpose of the procedure or treatment, the risks and benefits of the procedure, and alternatives, including the option of not proceeding with the test or treatment.

INFRASPINATUS. A muscle at the middle of the shoulder blade.

INFUSION. A medical treatment in which liquid substances are delivered into the body through various routes of administration.

INGUINAL. Referring to the groin area.

INGUINAL HERNIA. An opening, weakness, or bulge in the lining of the abdominal wall in the groin area, with protrusion of the large intestine.

INHALANT. Medicine that is breathed into the lungs.

INHALATION CHALLENGE TEST. A test given to diagnose asthma by asking the patient to breathe cold air, methacholine, histamine, or another airway irritant and then measuring the decline (if any) in the forced expiratory volume (FEV1).

INHALED CORTICOSTEROID (ICS). An inhaled asthma medication.

INHERITANCE PATTERN. The process by which an offspring acquires traits from parents; refers to dominant or recessive inheritance.

INHIBITION. Referring to the moment in an Alexander lesson when the student refrains from beginning a movement in order to avoid tensing of the muscles.

INJECTION. Forcing a fluid into the body by means of a needle and syringe.

INLAY. A filling that is made outside of the tooth and then cemented into place.

INNATE IMMUNE SYSTEM. The part of the immune system that responds to infectious organisms in a nonspecific manner. Natural killer cells are part of the innate immune system.

INNER EAR. The interior section of the ear, where sound vibrations and information about balance are translated into nerve impulses.

INNOCENT. The medical term for a harmless condition.

INORGANIC MERCURY. Inorganic compounds such as mercuric oxide (HgO) and mercuric chloride ($HgCl_2$).

INPATIENT SURGERY. Surgery that requires an overnight stay of one or more days in the hospital.

INSECTICIDE. A pesticide that kills insects.

INSIDIOUS. Progressing gradually and inconspicuously, but with serious effects.

INSIGHT-ORIENTED THERAPY. An approach to psychotherapy based on helping the client understand the existence of previously unconscious conflicts and the origin of maladaptive behavior in order to change it. Psychoanalysis is one form of insight-oriented therapy.

INSOMNIA. A sleep disorder characterized by inability either to fall asleep or to stay asleep.

INSPECTION. The visual examination of the body using the eyes and a lighted instrument if needed. The sense of smell may also be used.

INSTRUMENTAL ACTIVITIES OF DAILY LIVING (IADLS). Daily tasks that enable a person to live independently.

INSUFFLATION. Inflation of the abdominal cavity using carbon dioxide; performed prior to laparoscopy to give the surgeon space to maneuver surgical equipment.

INSULIN. A hormone produced by the pancreas that is central to the processing of sugars and carbohydrates in the diet.

INSULIN RESISTANCE. An inability to respond to insulin, a hormone produced by the pancreas that helps the body to use glucose.

WWW.BOOKBAZ.IR

INSULINOMA. Tumor that arises from the insulin-producing cells in the pancreas.

INTEGRASE INHIBITOR OR INTEGRASE STRAND TRANSFER INHIBITOR (INSTI). An antiretroviral drug, such as raltegravir, that disables integrase, a protein used by HIV to insert its genetic material into CD4 cells.

INTEGUMENT. A covering; in medicine, the skin as a covering for the body. The skin is also called the integumentary system.

INTEGUMENTARY. The integumentary system consists of the skin, the primary protective barrier between the body and the outside world.

INTELLECTUAL DISABILITY. Significant impairment in intellectual function and adaptation in society. Usually associated an intelligence quotient (IQ) below 70.

INTENTION TREMOR. A rhythmic purposeless shaking of the muscles that begins with purposeful (voluntary) movement. This tremor does not affect muscles that are resting.

INTERCEPTIVE ORTHODONTICS. Preventative orthodontics; early, simpler orthodontic treatment.

INTERDENTAL. Between the teeth.

INTERFERON. Potent immune-defense protein produced by viral-infected cells. Manufactured interferon is used as an anticancer and antiviral drug.

INTERFERON ALPHA. A chemical made naturally by the immune system and also manufactured as a drug.

INTERLEUKIN. Any of a group of cytokines that were first found to be expressed by white blood cells and help to regulate the responses of the immune system.

INTERLEUKIN-1 RECEPTOR ANTAGONIST (IL-1RA). A biologic medication that interferes with the activity of the inflammatory cytokine interleukin-1; used to treat rheumatoid arthritis.

INTERLEUKIN-2 (IL-2). A cytokine derived from T helper lymphocytes that causes proliferation of T-lymphocytes and activated B lymphocytes.

INTERLEUKINS (ILS). Cytokines involved in immune system regulation; IL-12 and IL-23 are overactive in psoriasis.

INTERMITTENT CATHETERIZATION. Periodic catheterization to facilitate urine flow.

INTERMITTENT CLAUDICATION. Leg pain and weakness caused by walking.

INTERMITTENT EXPLOSIVE DISORDER. A personality disorder in which an individual is prone to intermittent explosive episodes of aggression during which he or she causes bodily harm or destroys property.

INTERNAL DERANGEMENT. A condition in which the cartilage disc in the temporomandibular joint lies in front of its proper position.

INTERNALIZING DISORDERS. Disorders related to issues within the self; depression and the anxiety disorders are two common types of internalizing disorders.

INTERNATIONAL NORMALIZED RATIO (INR). A formula for adjusting variables affecting prothrombin time, so that results are comparable between laboratories and different regions; used primarily for patients taking warfarin.

INTERNATIONAL UNIT (IU). An agreed-upon standard of physiological activity for a given biological substance such as a vitamin.

INTERPERSONAL THERAPY. An approach that includes psychoeducation about the sick role, and emphasis on the present and improving interpersonal dynamics and relationships. Interpersonal therapy is effective in treating adjustment disorders related to physical illness.

INTERSEX. A term that is sometimes used to refer to having a sexual anatomy that is not standard for either a male or a female. It covers a number of different conditions but is considered a convenient umbrella term for discussing disorders of sex development.

INTERSTITIAL CYSTITIS. A chronic inflammatory condition of the bladder involving symptoms of bladder pain, frequent urination, and burning during urination.

INTERSTITIAL FLUID. The fluid between cells in tissues. Referred to as the liquid substance of the body.

INTERSTITIAL LUNG DISEASE. A category of lung disease that can lead to breathing or heart failure; injury or foreign substances in the lungs (such as asbestos fibers), infections, cancers, or inherited disorders may cause one of the 180 conditions classified as interstitial lung disease.

INTERSTITIAL RADIATION THERAPY. The process of placing radioactive sources directly into the tumor. These radioactive sources can be temporary (removed after the proper dose is reached) or permanent.

INTERSTITIAL SPACE. The fluid filled areas that surround the cells of a given tissue; also known as tissue space.

INTERVERTEBRAL DISK. The cylindrical elastic-like gel pad that connects and separates each pair of vertebrae in the spine.

INTESTINAL DYSBIOSIS. An imbalance among the various microorganisms that live in the digestive tract.

INTESTINAL MICROFLORA. The bacteria and other microorganisms that live in the human gastrointestinal tract.

INTESTINE. Commonly called the bowels, divided into the small and large intestine. They extend from the stomach to the anus.

INTOXICATION. The mental, physical, or emotional state produced by a substance.

INTRA-ABDOMINAL PRESSURE. Pressure that occurs within the abdominal cavity. Pressure in this area builds up with coughing, crying, and the pressure exerted when bearing down with a bowel movement.

INTRA-AORTIC BALLOON PUMP. A temporary device inserted into the femoral artery and guided upward to the aorta. The small balloon helps strengthen heart contractions by maintaining improved blood pressure.

INTRACAVITARY. Inside a space or cavity within the body.

INTRACELLULAR PARASITE. An organism which can only feed and live within the cell of a different animal.

INTRACEREBRAL HEMATOMA. Bleeding within the brain caused by trauma to a blood vessel.

INTRACEREBRAL HEMORRHAGE. A type of hemorrhagic stroke caused by bleeding within the brain.

INTRACRANIAL. Located within or on the surface of the brain.

INTRACRANIAL HYPERTENSION. Abnormally high blood pressure within the skull.

INTRACUTANEOUS. Into the skin, in this case directly under the top layer of skin.

INTRAMUSCULARLY. A medication given by needle into a muscle.

INTRAOCULAR. Literally, within the eye.

INTRAOCULAR LENS. Lens made of silicone or plastic placed within the eye; can be corrective.

INTRAOCULAR RETINOBLASTOMA. Cancer that is limited to the eye and has not spread to other parts of the body.

INTRATHECAL. Administration of chemotherapy drugs injected into the cerebrospinal fluids which surround the brain and spinal cord.

INTRATHECAL THERAPY. Injecting chemotherapy directly into the CSF using lumbar puncture.

INTRAUTERINE. Situated or occurring in the uterus.

INTRAUTERINE DEVICE (IUD). Contraceptive device consisting of a piece of bent plastic or metal that is inserted through the vagina into the uterus.

INTRAVENOUS. Into a vein.

INTRAVENOUS (IV). Into a vein; a needle is inserted into a vein in the back of the hand, inside the elbow, or some other location on the body. Fluids, nutrients, and drugs can be injected.

INTRAVENOUS (IV) THERAPY. Administration of intravenous fluids.

INTRAVENOUS PYELOGRAM (IVP). A procedure in which a dye is injected into a vein in the arm. The dye travels through the body and concentrates in the urine to be discharged. It outlines the kidneys, ureters, and the urinary bladder. An x-ray image is then made and any abnormalities of the urinary tract are revealed.

INTRAVENTRICULAR HEMORRHAGE (IVH). A condition in which blood vessels within the brain burst and bleed into the hollow chambers (ventricles) normally reserved for cerebrospinal fluid and into the tissue surrounding them.

INTRINSIC FACTOR. A substance produced by the parietal cells of the stomach. In order to be absorbed by the intestine, vitamin B_{12} must form a complex with intrinsic factor.

INTRINSIC PATHWAY. One of three pathways in the coagulation cascade.

INTRINSIC SPHINCTER DEFICIENCY (ISD). A factor in severe stress incontinence due to the inadequacy of the sphincter muscles to keep the bladder closed.

INTUBATION. A procedure where a tube is inserted through the mouth and into the trachea keep the airway open and to help the patient breathe.

INTUSSUSCEPTION. The slipping or telescoping of one part of the intestine into the section next to it.

WWW.BOOKBAZ.IR

INVASIVE. A descriptive term for thymoma that has spread beyond the outer wall of the thymus.

INVASIVE SURGERY. A form of surgery that involves making an incision in the patient's body and inserting instruments or other medical devices into it.

ION. An atom or group of atoms that acquires an electrical charge by the gain or loss of electrons.

IONIZING RADIATION. Radiation that can damage living tissue by disrupting and destroying individual cells at the molecular level. All types of nuclear radiation—x rays, gamma rays and beta rays—are potentially ionizing. Sound waves physically vibrate the material through which they pass, but do not ionize it.

IQ. Abbreviation for Intelligence Quotient. Compares an individual's mental age to his/her true or chronological age and multiplies that ratio by 100.

IRIDO CORNEAL ENDOTHELIAL SYNDROME (ICE). A type of glaucoma in which cells from the back of the cornea spread over the surface of the iris and tissue that drains the eye, forming adhesions that bind the iris to the cornea.

IRIS. The colored ring just behind the cornea and in front of the lens that controls the amount of light sent to the retina.

IRON OVERLOAD. A side effect of frequent blood transfusions in which the body accumulates abnormally high levels of iron. Iron deposits can form in organs, particularly the heart, and cause life-threatening damage.

IRON POISONING. A potentially fatal condition caused by swallowing large amounts of iron dietary supplements. Most cases occur in children who have taken adult-strength iron formulas. The symptoms of iron poisoning include vomiting, bloody diarrhea, convulsions, low blood pressure, and turning blue.

IRON-DEFICIENCY ANEMIA. The inability to make sufficient red blood cells, resulting in fatigue, shortness of breath, headaches, and an inability to fight infections. It is common in pregnancy.

IRRIGATION. In medicine, the practice of washing out or flushing a wound or body opening with a stream of water or another liquid.

IRRITABLE BOWEL DISEASE. An intestinal disorder often accompanied by abdominal pain and diarrhea.

ISCHEMIA. A localized deficiency in the blood supply, usually caused either by vasoconstriction or by obstacles to the arterial blood flow.

ISCHEMIC. A localized deficiency in the blood supply, usually caused either by vasoconstriction or by obstacles to the arterial blood flow.

ISCHEMIC HEART DISEASE. Insufficient blood supply to the heart muscle (myocardium).

ISCHEMIC STROKE. Insufficient blood supply to a part of the brain.

ISLETS OF LANGERHANS. Special structures in the pancreas responsible for insulin secretion among other functions. They are named for Paul Langerhans, the German researcher who first identified them in 1869.

ISOENZYME. One of a group of enzymes that bring about the same reaction but are vary in their physical properties.

ISOMETRIC EXERCISES. Exercises which strengthen through muscle resistance.

ISOSPORA BELLI. A type of parasitic protozoa.

ISOTOPE. Any of two or more species of atoms of a chemical element with the same atomic number and nearly identical chemical behavior but with differing atomic mass and physical properties.

ISOTRETINOIN. A drug for severe acne that decreases sebum production and dries up pimples.

IXODES. A genus of ticks that carry *Borrelia burgdorferi* and inject the bacteria into the host while feeding on blood.

J

JANUS KINASE (JAK) INHIBITOR. Tofacitinib (Xeljanz); a class of biologic for treating rheumatoid arthritis.

JARISCH-HERXHEIMER REACTION. A temporary reaction to penicillin treatment for syphilis that includes fever, chills, and worsening of the skin rash or chancre.

JAUNDICE. Yellowing of the eyes and skin due to the buildup of bilirubin in the blood.

JEJUNOSTOMY. Surgical creation of an opening to the middle portion of the small intestine (jejunum) through the abdominal wall.

JEJUNUM. The middle portion of the small intestine. It is approximately 8 ft (2.5 m) long and extends from the jejunum to the ileum.

JET LAG. A temporary disruption of the body's sleep-wake rhythm following high-speed air travel across several time zones. Jet lag is most severe in people who have crossed eight or more time zones in 24 hours.

JOINT. A structure that holds two or more bones together.

JOINT CONTRACTURES. Stiffness of the joints that prevents full extension.

JOINT DISLOCATION. The displacement of a bone.

K

KALLMANN SYNDROME. A rare genetic disorder in which the hypothalamus does not produce enough gonadotropin-releasing hormone, leading to under functioning of the testes in males and the ovaries in females.

KAPOSI'S SARCOMA. A rare connective tissue cancer that causes painless purplish-red (in light skin) or brown (in dark skin) blotches and is a major diagnostic marker of AIDS.

KARYOTYPE. A photomicrograph (picture taken through a microscope) of a person's 46 chromosomes, lined up in 23 pairs, that is used to identify some types of genetic disorders.

KARYOTYPING. A laboratory test used to study an individual's chromosome make-up. Chromosomes are separated from cells, stained, and arranged in order from largest to smallest so that their number and structure can be studied under a microscope.

KEGEL EXERCISES. Repetitive contractions to tone the pubococcygeal muscle of the pelvic floor for enhancing sexual response during intercourse or controlling incontinence.

KELOID. A thick scar.

KERATIN. A tough, nonwater-soluble protein found in the nails, hair, and the outermost layer of skin. Human hair is made up largely of keratin.

KERATINOCYTE. The basic type of cell in the epidermis (uppermost layer) of the skin, comprising about 90% of its cells.

KERATOCONJUNCTIVITIS. Inflammation of the conjunctiva and cornea of the eye.

KERATOCONUS. An eye condition in which the cornea bulges outward, interfering with normal vision. Usually both eyes are affected.

KERATODERMA BLENNORRHAGICA. The medical name for the patches of scaly skin that occur on the arms, legs, and trunk of RS patients.

KERATOLYTIC. An agent that dissolves or breaks down the outer layer of skin (keratins).

KERION. A raised boggy or swollen patch of reddened skin that develops as a complication of ringworm.

KERNICTERUS. A serious condition in which bilirubin deposits in the brain leading to permanent neurological damage and potentially death.

KETOACIDOSIS. An abnormal metabolic condition in which the body fails to regulate the production of ketone bodies, leading to a drop in the pH of the blood.

KETOGENIC DIET. A diet abnormally high in fat and low in carbohydrates and protein that produces ketosis and alters the acid-base balance in the body.

KETONE BODIES. Water-soluble molecules produced by the liver from fatty acids during periods of starvation or calorie-reduction dieting coupled with restricted intake of carbohydrates.

KETONES. Poisonous acidic chemicals produced by the body when fat instead of glucose is burned for energy. Breakdown of fat occurs when not enough insulin is present to channel glucose into body cells.

KETOSIS. An abnormal increase in the number of ketones in the body, produced when the liver breaks down fat into fatty acids and ketone bodies. Ketosis is a common side effect of low-carbohydrate diets or uncontrolled diabetes If continued for a long period of time, ketosis can cause serious damage to the kidneys and liver.

KIDNEY. Either of two organs in the lumbar region that filter the blood, excreting the end products of the body's metabolism in the form of urine and regulating the concentrations of hydrogen, sodium, potassium, phosphate, and other ions in the body.

KIDNEY (RENAL) DISEASE. Any disorder that impairs the kidney's ability to remove waste and toxins from the body.

KIDNEY FAILURE. The inability of the kidney to excrete toxic substances from the body.

KIDNEY STONE. A hard mass that forms in the urinary tract that can cause pain, bleeding, obstruction, and/or infection. Stones are primarily composed of calcium.

WWW.BOOKBAZ.IR

KIDNEYS. The pair of bean-shaped organs, located below the ribs toward the middle of the back, which cleanse the blood, regulate acid concentration, and maintain water balance in the body through the formation of urine.

KIESSELBACH'S PLEXUS. An area on the anterior part of the nasal septum that has a rich supply of blood vessels and is a common site of nosebleeds. It is named for Wilhelm Kiesselbach, a nineteenth-century German otolaryngologist.

KILOGRAM. Metric unit of weight equal to 1,000 grams or 2.2046 lb.

KINESIOLOGY. The study of the anatomy and physiology of body movement, particularly in relation to therapy.

KLEINE-LEVIN SYNDROME. A disorder that occurs primarily in young males, three or four times a year. The syndrome is marked by episodes of hypersomnia, hypersexual behavior, and excessive eating.

KLEPTOMANIA. An impulse control disorder in which one steals objects that are of little or no value.

KLINEFELTER SYNDROME. A condition caused by extra X chromosome(s) in a male, that results in small testes and infertility together with increased height, decreased facial hair, and sometimes breast enlargement.

KLINEFELTER'S SYNDROME. Chromosomal abnormality characterized by small testes and male infertility.

KOCK POUCH. A type of ileostomy in which the surgeon forms an artificial rectum from a section of the ileum. A Kock pouch is sometimes called a continent ileostomy because it is drained with a tube.

KOH. The chemical formula for potassium hydroxide, which is used to perform the KOH test. The test is also called a potassium hydroxide preparation.

KOPLIK'S SPOTS. Tiny spots occurring inside the mouth, especially on the inside of the cheek. These spots consist of minuscule white dots (like grains of salt or sand) set onto a reddened bump. Unique to measles.

KWASHIORKOR. Severe malnutrition in children primarily caused by a protein-poor diet, characterized by growth retardation.

KYPHOSCOLIOSIS. Abnormal front-to-back and side-to-side curvature of the spine.

KYPHOSIS. An abnormal outward curvature of the spine, with a hump at the upper back.

L

LABIA. The fatty folds of the vulva.

LABIA MAJORA. Major lips; mounds of tissue forming the lateral boundaries of the vulva.

LABIA MINORA. Minor lips; narrow folds of tissue between the labia major, on either side of the urethral and vaginal openings.

LABOR. The process during which the uterus contracts, and the cervix opens to allow the passage of a baby into the vagina.

LABYRINTH. The bony cavity of the inner ear.

LACERATION. A cut in the skin.

LACRIMAL DUCT. A short canal leading from a small orifice at the medial angle of each eyelid to the lacrimal sac.

LACRIMAL GLAND. An almond-shaped gland that secretes tears.

LACRIMAL SAC. The dilated upper end of the nasolacrimal duct in which the lacrimal ducts empty.

LACTASE ENZYME. The enzyme produced by cells that line the small intestine which allows the body to break down lactose.

LACTATE DEHYDROGENASE (LDH). An enzyme that can be a marker in the blood for some cancers.

LACTATION. Secretion of milk from the breasts; the act of breastfeeding.

LACTIC ACIDOSIS. A serious condition caused by the build up of lactic acid in the blood, causing it to become excessively acidic. Lactic acid is a by-product of glucose metabolism.

LACTOBACILLUS ACIDOPHILUS. A bacteria found in yogurt that changes the balance of the bacteria in the intestine in a beneficial way.

LACTOSE. A sugar made up of glucose and galactose. It is the primary sugar in milk.

LACTOSE INTOLERANCE. An inability to properly digest milk and dairy products.

LACTOVEGETARIAN. A vegetarian who uses milk and cheese in addition to plant-based foods.

LAMELLAR ICHTHYOSIS. Also called fish scale disease, this inherited condition is characterized by darkened, scaly, dry patches of skin.

LAMINA. The broad plates of bone on the upper surface of the vertebrae that fuse together at the midline to form a bony covering over the spinal canal.

LAMINARIA. A medical product made from a certain type of seaweed that is physically placed near the cervix to cause it to dilate.

LAMINECTOMY. Surgical removal of the lamina to reach and remove a herniated disk.

LAMINOTOMY. A less invasive alternative to a laminectomy in which a hole is drilled through the lamina.

LANDMARK. In superficial anatomy, any prominent physical feature that can be used to evaluate underlying tissues or organs without dissection.

LAPAROSCOPE. An instrument that enables the surgeon to see inside the abdominal cavity by means of a thin tube that carries an image to a television monitor.

LAPAROSCOPIC CHOLECYSTECTOMY. Removal of the gallbladder using a laparoscope, a fiber-optic instrument inserted through the abdomen.

LAPAROSCOPY. A minimally-invasive surgical or diagnostic procedure that uses a flexible endoscope (laparoscope) to view and operate on structures in the abdomen.

LAPAROTOMY. A surgical incision into the abdomen, made between the ribs and the pelvis, that offers surgeons a view inside the abdominal cavity.

LARGE CORE NEEDLE BIOPSY. A procedure using a thicker needle to remove a core of tissue, about the size of a grain of rice, from the breast.

LARGE INTESTINE. The portion of the colon that includes the cecum; ascending, transverse, and descending sigmoid colon; rectum; and anal canal.

LARVA. The immature, early form of an organism that at birth or hatching is not like its parent and has to undergo metamorphosis before assuming adult features.

LARYNGECTOMY. Surgical removal of the larynx to treat cancer.

LARYNGITIS. Inflammation of the larynx (voice box).

LARYNGOSCOPE. A diagnostic instrument that is used to examine the interior of the larynx.

LARYNGOSCOPY. A medical procedure that uses flexible, lighted, narrow tubes inserted through the mouth or nose to examine the larynx and other areas deep inside the neck.

LARYNGOSPASM. Spasmodic closure of the larynx.

LARYNX. A part of the respiratory tract between the pharynx and the trachea, having walls of cartilage and muscle and containing the vocal cords.

LASER. A device that emits electromagnetic radiation at specific wavelengths, usually in the ultraviolet, visible, or infrared regions of the spectrum.

LASER CYCLOPHOTOCOAGULATION. A procedure used for severe glaucoma in patients who have not responded well to previous treatments. The laser partially destroys the tissues that make the fluid of the eye.

LASER PERIPHERAL IRIDOTOMY. This procedure makes a drainage hole in the iris allowing the fluid to drain from the eye.

LASER TRABECULOPLASTY. In this procedure the laser attempts to open the normal drainage channels of the eye so fluid can drain more effectively.

LASER-ASSISTED IN SITU KERATOMILEUSIS (LASIK). A surgical procedure that uses a cutting tool and a laser to modify the cornea and correct moderate to high levels of myopia.

LASER-ASSISTED SUB-EPITHELIAL KERATOMILEUSIS (LASEK). A surgical procedure in which the epithelium is loosened on the corneal surface. The loosened epithelium is then reflected away from the cornea, and laser ablation performed.

LATARJET'S NERVE. Terminal branch of the anterior vagal trunk, which runs along the lesser curvature of the stomach.

LATCH-ON. The process whereby the baby opens the mouth widely and first exerts negative pressure on the mother's nipple and then positive pressure. Good latch-on will result in adequate transfer of milk into the baby's mouth and prevent sore nipples from occurring.

LATE DECELERATION. Transient slowing of the fetal heart (brachycardia), which reaches its height more than 30 seconds after the peak of the uterine contraction and may indicate the fetus is not receiving enough oxygen (hypoxia).

LATENCY. The period of inactivity between the time a stimulus is provided and the time a response occurs.

WWW.BOOKBAZ.IR

LATENT VIRUS. An inactive virus which is in a dormant state within a cell. Herpes virus is latent in cells of the nervous system.

LATEX. A milky white fluid, or sap, from certain plants that makes up certain rubber products.

LAVAGE. Washing out.

LAW OF SIMILARS. The basic principle of homeopathic medicine that governs the selection of a specific remedy. It holds that a substance of natural origin that produces certain symptoms in a healthy person will cure those same symptoms in a sick person.

LAXATIVE. An agent that stimulates defecation.

LDL CHOLESTEROL. Low-density lipoprotein cholesterol is the primary cholesterol molecule. High levels of LDL increase the risk of coronary heart disease. LDL is nicknamed "bad" cholesterol.

LEAD. Name given the electrode when it is attached to the skin.

LEARNING DISABILITIES. An impairment of the cognitive processes of understanding and using spoken and written language that results in difficulties with one or more academic skill sets (e.g., reading, writing, mathematics).

LEARNING DISORDERS. Academic difficulties experienced by children and adults of average to above-average intelligence that involve reading, writing, and/or mathematics, and which significantly interfere with academic achievement or daily living.

LEFT VENTRICLE. The large chamber on the lower left side of the heart. The left ventricle sends blood to the aorta and the rest of the body.

LEGIONELLOSIS. A disease caused by infection with a Legionella bacterium.

LEISHMAN-DONOVAN BODY. A body of a (trypanosomatid) protozoa at a particular and characteristic stage in its life cycle; the infectious (trypanosomatid) protozoa can cause leishmaniasis, and is relatively easy to identify at that stage.

LENS. A device that bends light waves.

LENS (THE CRYSTALLINE LENS). The transparent, elastic, curved structure behind the iris (colored part of the eye) that helps focus light on the retina.

LENTICONUS. A rare, usually congenital, condition in which the surface of the lens of the eye is conical.

LEPTIN. A peptide hormone produced by fat cells that acts on the hypothalamus to suppress appetite and burn stored fat.

LESION. Any visible, local abnormality of the tissues of the skin, such as a wound, sore, rash, or boil.

LET. A topical anesthetic mixture containing lidocaine, epinephrine, and tetracaine.

LETHARGY. The state of being sluggish.

LEUKEMIA. A cancer of blood cells characterized by the abnormal increase in the number of white blood cells in the tissues. There are many types of leukemias and they are classified according to the type of white blood cell involved.

LEUKEMIA STAINS. Special stains added to smears of blood or bone marrow, performed to diagnose and classify leukemia.

LEUKOCORIA. A pupil reflex that is white instead of red or that has white spots.

LEUKOCYTE. A white blood cell protects the body against infection and fight infection when it occurs. They are bigger than red blood cells.

LEUKOCYTE ADHESION DEFICIENCY SYNDROME. A complement deficiency syndrome characterized by recurrent infections of the skin, mucous membranes, and gastrointestinal tract and the absence of pus formation. This disorder is sometimes apparent at birth when separation of the umbilical cord takes longer than normal.

LEUKOCYTE ALKALINE PHOSPHATASE (LAP) TEST. A blood test that measures the level of enzyme activity in a type of white blood cell called neutrophils.

LEUKOCYTOSIS. An increase in the number of leukocytes in the blood.

LEUKODYSTROPHY. Any of several inherited diseases characterized by the degeneration of myelin in the brain, spinal cord, and peripheral nerves.

LEUKOPENIA. A decrease in the number of white blood cells in the blood.

LEUKOPLAKIA. A flat whitish-colored area of the oral mucosa that is not caused by thrush or any other specific disease.

LEUKOTRIENE. A chemical produced by immune system cells and lung tissue that is involved in allergic responses.

LEUKOTRIENE RECEPTOR ANTAGONIST (LTRA). An asthma medication that controls airway inflammation by blocking the action of leukotrienes.

LEVODOPA (L-DOPA). A substance used in the treatment of Parkinson's disease. Levodopa can cross the blood-brain barrier that protects the brain. Once in the brain, it is converted to dopamine and thus can replace the dopamine lost in Parkinson's disease.

LEVONORGESTREL. A synthetic progestin used in ECPs.

LEWY BODIES. Areas of injury found on damaged nerve cells in certain parts of the brain associated with major neurocognitive disorder.

LEYDIG CELLS. Cells that make up the endocrine tissue of the testis and produce testosterone. They are named for Franz von Leydig (1821–1908), the German professor of anatomy who first identified them.

LICENSED PRACTICAL NURSE (LPN). A person who is licensed to provide basic nursing care under the supervision of a physician or a registered nurse.

LICHEN PLANUS. An uncommon disorder involving a recurrent, itchy, inflammatory rash or lesion on the skin or in the mouth. The exact cause is unknown, but the disorder is likely to be related to an allergic or immune reaction. The skin lesions are distinct from other disorders.

LI-FRAUMENI SYNDROME. A hereditary cancer predisposition syndrome that increases a person's risk of breast cancer, brain cancer, and osteosarcoma.

LIGAMENT. A type of connective tissue that connects bones or cartilage and provides support and strength to joints.

LIGAMENTA FLAVA. A series of bands of tissue that are attached to the vertebrae in the spinal column. They help to hold the spine straight and to close the spaces between the laminar arches. The Latin name means "yellow band(s)."

LIMB-GIRDLE MUSCULAR DYSTROPHY (LGMD). Form of muscular dystrophy that begins in late childhood to early adulthood and affects both men and women, causing weakness in the muscles around the hips and shoulders.

LIMBIC SYSTEM. A group of structures in the brain that includes the hypothalamus, amygdala, and hippocampus. The limbic system plays an important part in regulation of human moods and emotions. Many psychiatric disorders are related to malfunctioning of the limbic system.

LIMITED SCLERODERMA. A subtype of systemic scleroderma with limited skin involvement. It is sometimes called the CREST form of scleroderma, after the initials of its five major symptoms.

LINDANE. An organic chloride, neurotoxic insecticide that kills lice.

LINGUAL TONSILS. A pair of small tonsils located on the upper side of the base of the tongue.

LINOLEIC ACID. An unsaturated omega-6 fatty acid found in many plant oils that humans need in their diet. Plant oils rich in linoleic acid are beneficial to the skin when used in massage.

LIPID. Any organic compound that is greasy and insoluble in water but soluble in alcohol. Fats, waxes, and oils are examples of lipids.

LIPODYSTROPHY. A redistribution of body fat caused by AIDS or HAART.

LIPOMA. A usually benign tumor of fatty tissue.

LIPOPROTEIN. A chemical combination of a protein and a lipid (fats).

LIPOSHAVING. Involves removing fat that lies closer to the surface of the skin by using a needle-like instrument that contains a sharp-edged shaving device.

LIPOSUCTION. A surgical technique for removing fat from under the skin by vacuum suctioning.

LISTERIOSIS. A usually mild illness caused by food poisoning with *Listeria monocytogenes*, but which can be serious or fatal in newborns, the elderly, and the immunocompromised and which can cause miscarriage, stillbirth, or premature birth if contracted during pregnancy.

LITHIUM. A drug used to treat manic depression (bipolar disorder) that can be transmitted in breast milk.

LITHOTRIPSY. A nonsurgical technique for removing gallstones by breaking them apart with high-frequency sound waves.

LIVER. A solid organ located on the right in the upper abdomen. It plays a major role in metabolism, digestion, detoxification, and elimination of substances from the body.

LIVER BIOPSY. A surgical procedure where a small piece of the liver is cut out for examination. A needle or narrow tube may be inserted either directly through the skin and muscle or through a small incision and passed into the liver for collection of a sample of liver tissue.

WWW.BOOKBAZ.IR

LIVER ENCEPHALOPATHY. A condition in which the brain is affected by a buildup of toxic substances that would normally be removed by the liver. The condition occurs when the liver is too severely damaged to cleanse the blood effectively.

LIVER FUNCTION TESTS. Tests used to evaluate liver metabolism, storage, filtration, and excretion. The tests include alkaline phosphatase and serum alanine aminotransferase and aspartate aminotransferase.

LOBAR. Relating to a lobe, a rounded projecting part of the lungs.

LOBAR HEMORRHAGE. Bleeding into one of the lobes of the brain.

LOBULAR CARCINOMA. Breast cancer that originates in the milk glands.

LOBULAR CARCINOMA-IN-SITU (LCIS). Breast cancer that is confined to the milk-producing glands.

LOBULES. A small lobe or subdivision of a lobe (often on a gland) that may be seen on the surface of the gland by bumps or bulges.

LOCAL ANESTHETIC. A liquid used to numb a small area of the skin.

LOCALIZED. Confined to a small area.

LOCALIZED SCLERODERMA. Thickening of the skin from overproduction of collagen.

LOCUS CERULEUS. Area in the brain stem that processes sensory signals from all areas of the body.

LODESTONE. A variety of magnetite that possesses magnetic polarity.

LOEFFLER'S MEDIUM. A special substance used to grow diphtheria bacilli to confirm a diagnosis.

LOEFFLER'S SYNDROME. The respiratory phase of ascariasis, marked by inflammation of the lungs and eosinophilia.

LONG QT SYNDROME. A rare inherited heart condition in which a disorder of the heart rhythm results in rapid, chaotic heartbeats that can lead to a fainting spell or even sudden death. Certain medications can also trigger the condition. The phrase "long QT" refers to the pattern of this abnormal heartbeat as it appears on an electrocardiogram.

LONG-ACTING BETA-AGONIST (LABA). An inhaled bronchodilator, often used in combination with a corticosteroid for asthma.

LONG-STRETCH BANDAGES. Specialized bandages, similar to an Ace bandage, that have 100–200% stretch.

LOOP ELECTROSURGICAL EXCISION (LEEP). A procedure that can help diagnose and treat cervical abnormalities using a thin wire loop that emits a low-voltage high-frequency radio wave that can excise tissue.

LOW TRANSVERSE INCISION. An incision made horizontally across the lower end of the uterus in cesarean delivery.

LOW-DENSITY LIPOPROTEIN (LDL). A type of lipoprotein that transports cholesterol through the bloodstream. LDL cholesterol is known as "bad", because it can cause atherosclerosis, which is associated with cardiovascular disease.

LOW-DOSE COMPUTED TOMOGRAPHY (LDCT). A lung-cancer screen using multiple low-dose x rays.

LOWER ESOPHAGEAL SPHINCTER (LES). A muscular ring at the base of the esophagus that keeps stomach contents from entering back into the esophagus.

LOWER EXTREMITY AMPUTATION. To cut a limb from the body.

LOW-STRETCH BANDAGE. Specialized bandages, with 30–90% stretch, that are used to obtain the correct compression during the treatment of lymphedema; also known as short-stretch bandages.

LUES MALIGNA. Areas of ulcerated and dying skin tissue that may occur with secondary syphilis, most frequently in HIV-positive patients.

LUGOL'S SOLUTION. A strong iodine solution.

LUMBAR. Pertaining to the part of the back between the chest and the pelvis.

LUMBAR PUNCTURE (LP). Also called a spinal tap, a procedure in which a thin needle is used to withdraw a sample of cerebrospinal fluid for diagnostic purposes from the area surrounding the spine.

LUMBAR SPINE. The segment of the human spine above the pelvis that is involved in low back pain. There are five vertebrae, or bones, in the lumbar spine.

LUMBAR VERTEBRAE. The vertebrae of the lower back below the level of the ribs.

LUMBOSACRAL. Referring to the lower part of the backbone or spine.

LUMEN. The cavity or channel inside a blood vessel or tube-shaped organ.

LUMPECTOMY. Breast-conserving surgery that removes only the cancerous tumor and a limited amount of normal surrounding tissue.

LUNG ALLOCATION SCORE (LAS). A numerical value from 0 to 100 calculated to determine a patient's priority to receive a donor lung within the United States. The LAS system has been used by the United Network for Organ Sharing (UNOS) since 2005.

LUNG FUNCTION TESTS. Tests of how much air the lungs can move in and out, and how quickly and efficiently this can be done. Lung function tests are usually done by breathing into a device that measures air flow.

LUPUS ERYTHEMATOSUS. A chronic inflammatory disease in which inappropriate immune system reactions cause abnormalities in the blood vessels and connective tissue.

LUTEINIZING HORMONE. A hormone secreted by the pituitary gland that regulates the menstrual cycle and triggers ovulation in females. In males it stimulates the testes to produce testosterone.

LUTEINIZING HORMONE-RELEASING HORMONE (LH-RH) AGONIST. A substance that blocks the action of LHRH, a hormone that stimulates the production of testosterone (a male hormone) in men. Used to treat prostate cancers that require testosterone for growth.

LUTROPIN. Another term for luteinizing hormone, this hormone stimulates the development and release of the egg from the ovary.

LUX. The International System unit for measuring illumination, equal to one lumen per square meter.

LUXATE. To loosen or dislocate a tooth from its socket.

LYME DISEASE. An acute disease which is usually marked by skin rash, fever, fatigue, and chills. Left untreated, it may cause heart and nervous system damage.

LYMPH. This is a clear, colorless fluid found in lymph vessels and nodes. The lymph nodes contain organisms that destroy bacteria and other disease causing organisms (also called pathogens).

LYMPH CHANNELS. The vessels that transport lymph throughout the body. Lymph is a clear fluid that contains cells important in forming antibodies that fight infection.

LYMPH NODE. A small structure located throughout the body (part of the lymphatic system) designed to filter the flow of lymph, a usually clear fluid that originates from stem cells.

LYMPH NODE DISSECTION. The removal of underarm lymph nodes to check for the spread of cancer.

LYMPH SYSTEM. When sickness or infection invades the body, the immune system is the first line of defense. A big part of that defense is the lymph system. Lymph is carried through the body by lymph vessels that have valves and muscles to help move the fluid. Along the route are lymph nodes that serve as filters for harmful substances. This network of vessels and nodes together is called the lymph system.

LYMPH/LYMPHATIC. One of the three body fluids that is transparent and a slightly yellow liquid that is collected from the capillary walls into the tissues and circulates back to the blood supply.

LYMPHANGIOGRAPHY. Injection of dye into lymphatic vessels followed by x rays of the area. It is a difficult procedure, as it requires surgical isolation of the lymph vessels to be injected.

LYMPHANGITIS. Inflammation of the lymphatic vessels. It often occurs together with lymphadenitis.

LYMPHATIC FLUID. The clear fluid found outside the cells which bathes the tissues. It is collected, filtered, and transported by the lymphatic system from around the tissues to the blood circulatory system. Fluid that collects as a result of lymphedema.

LYMPHATIC SYSTEM. A network composed of vessels, lymph nodes, the tonsils, the thymus gland, and the spleen. It is responsible for transporting fluid and nutrients to the bloodstream and for maturing certain blood cells that are part of the body's immune system.

LYMPHATIC VESSELS. Vessels that carry a fluid called lymph from the tissues to the bloodstream.

LYMPHATICS. Channels that are conduits for lymph.

LYMPHEDEMA. The unnatural accumulation of lymph in the tissues of the body, which results in swelling in that area.

LYMPHOCYTE. A class of white blood cell that is responsible for the immune response to antigens.

LYMPHOCYTOSIS. A condition in which the number of lymphocytes increases above normal levels.

LYMPHOID. Tissues relating to the lymphatic system. A thin, yellowish fluid called lymph fluid, travels throughout the body. The lymphatic system helps control fluids in the body.

WWW.BOOKBAZ.IR

LYMPHOID TISSUE. Sites within the body that produce cells of the immune system, including lymph nodes, bone marrow, and the thymus.

LYMPHOMA. A type of cancer that affects lymph cells and tissues, including certain white blood cells (T cells and B cells), lymph nodes, bone marrow, and the spleen. Abnormal cells (lymphocyte/leukocyte) multiply uncontrollably.

LYMPHOPENIA. A condition in which the number of lymphocytes falls below normal levels.

LYMPHOPROLIFERATIVE. An increase in the number of lymphocytes. Lymphocytes are a white blood cell (WBC) formed in lymphatic tissue throughout the body—in the lymph nodes, spleen, thymus, tonsils, Peyer patches, and sometimes in bone marrow.

LYMPHOSCINTIGRAPHY. A technique in which a radioactive substance that concentrates in the lymphatic vessels is injected into the affected tissue and mapped using a gamma camera, which images the location of the radioactive tracer.

LYSOSOME. Membrane-enclosed compartment in cells, containing many hydrolytic enzymes; where large molecules and cellular components are broken down.

LYSSAVIRUS. A genus of viruses that includes the rabies virus and related viruses that infect insects as well as mammals.

LYSYL OXIDASE. An enzyme required for the cross-linking of elastin and collagen molecules to form properly functioning connective tissue; present in relatively low levels in at least some forms of cutis laxa.

M

M PROTEIN. Monoclonal or myeloma protein; IgM that is overproduced in Waldenstrom's macroglobulinemia and accumulates in the blood and urine.

MACROBIOTIC DIET. A diet based primarily on whole grains, vegetables, and beans, and avoiding refined or processed foods. It is sometimes recommended by practitioners of alternative medicine as a preventive for cancer.

MACROCYTIC. A descriptive term applied to a larger than normal red blood cell.

MACROMASTIA. Excessive size of the breasts.

MACROPHAGE. A large white blood cell, found primarily in the bloodstream and connective tissue, that ingests disease-causing organisms.

MACROPODS. Derived from the Greek, macropod literally means "large footed." Macropods are marsupials belonging to the family Macropodidae, which includes kangaroos, wallabies, tree kangaroos, pademelons, and several others.

MACULA. The sensitive center of the retina that is responsible for detailed central vision.

MACULE. A flat, discolored area on the skin.

MACULOPAPULAR RASH. A rash characterized by raised, spotted lesions.

MAGNETIC FIELD. The three-dimensional area surrounding a magnet, in which its force is active. During MRI, the patient's body is permeated by the force field of a superconducting magnet.

MAGNETIC RESONANCE ANGIOGRAPHY. A noninvasive diagnostic technique that uses radio waves to map the internal anatomy of the blood vessels.

MAGNETIC RESONANCE IMAGING (MRI). An imaging technique that uses electromagnetic radiation and a computer to obtain detailed images of soft tissues such as the brain.

MAJOR DEPRESSIVE DISORDER. A mood disorder characterized by profound feelings of sadness or despair.

MAJOR TRANQUILIZERS. The family of drugs that includes the psychotropic or neuroleptic drugs, sometimes used to help autistic people. They carry significant risk of side effects, including Parkinsonism and movement disorders, and should be prescribed with caution.

MALABSORPTION. Poor absorption of nutrients.

MALABSORPTION SYNDROME. A condition characterized by indigestion, bloating, diarrhea, loss of appetite, and weakness, caused by poor absorption of nutrients from food as a result of HIV infection or giardiasis or other opportunistic infections of the digestive tract.

MALABSORPTIVE. A type of bariatric surgery in which a part of the stomach is partitioned off and connected to a lower portion of the small intestine in order to reduce the amount of nutrients that the body absorbs from food.

MALADAPTIVE. Unsuitable or counterproductive; for example, maladaptive behavior is behavior that is inappropriate to a given situation.

MALAISE. a general feeling of unwellness.

MALARIA. A serious disease prevalent in the tropics. It is caused by parasites and produces severe fever and sometimes complications affecting the kidneys, liver, brain, and blood. It is spread by the Anopheles mosquito and can be fatal.

MALATHION. An organic phosphate, neurotoxic insecticide that kills lice.

MALIGNANCY. A locally invasive and destructive growth.

MALIGNANT. Cancerous. Cells tend to reproduce without normal controls on growth and form tumors or invade other tissues.

MALIGNANT HYPERTHERMIA. A type of reaction (probably with a genetic basis) that can occur during general anesthesia in which the patient experiences a high fever, the muscles become rigid, and the heart rate and blood pressure fluctuate.

MALIGNANT MELANOMA. A potentially fatal form of skin cancer that develops from melanocytes, which are skin cells containing melanin.

MALIGNANT MESOTHELIOMA. A cancer of the pleura (the membrane lining the chest cavity and covering the lungs) that typically is related to asbestos exposure.

MALIGNANT TUMOR. An abnormal proliferation of cells that can spread to other sites.

MALINGERING. Pretending to be sick in order to be relieved of an unwanted duty or obtain some other obvious benefit.

MALLEUS. One of the three bones of the middle ear. It is also known as the ''hammer.''

MALLORY-WEISS SYNDROME. Bleeding from small tears in the gastric mucosa at the junction of the esophagus and the upper portion of the stomach. Mallory-Weiss syndrome commonly results from repeated retching, coughing, or vomiting associated with chronic alcoholism.

MALNUTRITION. Any disorder of nutrition caused by insufficient or unbalanced diet that can result in impaired absorption or use of foods.

MALOCCLUSION. The misalignment of opposing teeth in the upper and lower jaws.

MAMMARY ARTERY. A chest wall artery that descends from the aorta and is commonly used for bypass grafts.

MAMMARY HYPERPLASIA. Increased size of the breast.

MAMMOGRAM. A set of x rays taken of the front and side of the breast; used to diagnose various abnormalities of the breast.

MAMMOGRAPHY. X-ray screening to detect breast cancer.

MAMMOPLASTY. Surgery performed to change the size or shape of breasts.

MAMMOTOME. A method for removing breast biopsies using suction to draw tissue into an opening in the side of a cylinder inserted into the breast tissue. A rotating knife then cuts tissue samples from the rest of the breast; also known as a vacuum-assisted biopsy.

MANAGED CARE. The integration of financing and delivery of health care.

MANDALA. A design, usually circular, that appears in religion and art. In Buddhism and Hinduism, the mandala has religious ritual purposes and serves as a yantra (a geometric emblem or instrument of contemplation).

MANDIBLE. The lower jaw, a U-shaped bone attached to the skull at the temporomandibular joints.

MANIA. A mood disorder in which a person experiences prolonged elation or irritability characterized by overactivity that can lead to exhaustion and medical emergencies.

MANOMETER. A device used to measure fluid pressure.

MANOMETRY. Pressure measurement.

MANTOUX OR PPD TEST. Other names for a tuberculin skin test. PPD stands for purified protein derivative.

MANTOUX TEST. Another name for the PPD test.

MANTRA. A sacred word or formula repeated over and over to concentrate the mind.

MAO-B INHIBITORS. Inhibitors of the enzyme monoamine oxidase B. MAO-B helps break down dopamine; inhibiting it prolongs the action of dopamine in the brain.

MARASMUS. Severe malnutrition in children caused by a diet lacking in calories as well as protein. Marasmus may also be caused by disease and parasitic infection.

WWW.BOOKBAZ.IR

MARFAN SYNDROME. An inheritable disorder that affects the skeleton, joints, and blood vessels. Major indicators are excessively long arms and legs, lax joints, and vascular defects.

MARGIN OF RESECTION. The area between the cancerous tumor and the edges of the removed tissue.

MARSUPIALIZATION. Cutting out a wedge of the cyst wall and putting in stitches so the cyst cannot reoccur.

MARTIAL ARTS. Group of diverse activities originating from the ancient fighting techniques of the Orient.

MASS SPECTROMETRY. A method of analyzing a test sample by converting a portion of the sample into charged ions and measuring the electric current produced when the charged ions strike a detector. Mass spectrometry can be used to measure the quantity as well as the identity of a substance in the test sample.

MASSETER SPASM. Stiffening of the jaw muscles. Often one of the first symptoms of malignant hyperthermia susceptibility that occurs after exposure to a trigger drug.

MAST CELL. A type of immune system cell that displays immunoglobulin E (IgE) on its cell surface and participates in allergic reactions and asthma by releasing histamine and other chemicals from intracellular granules.

MASTECTOMY. Surgical removal of part or all of the breast and possibly associated lymph nodes and muscle.

MASTOID AIR CELLS. Numerous small intercommunicating cavities in the mastoid process of the temporal bone that empty into the mastoid antrum.

MASTOID ANTRUM. A cavity in the temporal bone of the skull, communicating with the mastoid cells and with the middle ear.

MASTOID BONE. The prominent bone behind the ear that projects from the temporal bone of the skull.

MASTOIDITIS. An inflammation of the bone behind the ear (the mastoid bone) caused by an infection spreading from the middle ear to the cavity in the mastoid bone.

MASTOPEXY. Surgical procedure to lift up a breast; may be used on opposite breast to achieve symmetrical appearance with a reconstructed breast.

MATERNAL. From one's mother.

MATERNAL BLOOD SCREENING. Maternal blood screening is normally done early in pregnancy to test for a variety of conditions. Abnormal amounts of certain proteins in a pregnant woman's blood raise the probability of fetal defects. Amniocentesis is recommended if such a probability occurs.

MATERNAL SERUM ANALYTE SCREENING. A medical procedure in which a pregnant woman's blood is drawn and analyzed for the levels of certain hormones and proteins. These levels can indicate whether there may be an abnormality in the unborn child. This test is not a definitive indicator of a problem and is followed by more specific testing such as amniocentesis or chorionic villus sampling.

MATERNAL UNIPARENTAL DISOMY. Chromosome abnormality in which both chromosomes in a pair are inherited from one's mother.

MATERNITY. Refers to the mother.

MATRIX. The tissue at the base of the nail, from which the nail grows.

MAXILLA. The bone of the upper jaw, which serves as a foundation of the face and supports the orbits.

MAXILLARY SINUSES. Sinuses located in the cheek under the eye next to the ethmoid sinus.

MAZE PROCEDURE. A surgical procedure used to treat atrial fibrillation. During the procedure, precise incisions are made in the right and left atria to interrupt the conduction of abnormal impulses. When the heart heals, scar tissue forms and the abnormal electrical impulses are blocked from traveling through the heart.

MCCUNE-ALBRIGHT SYNDROME (MCAS). A genetic syndrome characterized in girls by the development of ovarian cysts and puberty before the age of eight, together with abnormalities of bone structure and skin pigmentation.

MCH–1. Major histocompatibility complex proteins that protect cells from invasion.

MEAN CORPUSCULAR HEMOGLOBIN (MCH). A measurement of the average weight of hemoglobin in a red blood cell.

MEAN CORPUSCULAR HEMOGLOBIN CONCENTRATION (MCHC). The measurement of the average concentration of hemoglobin in a red blood cell.

MEAN CORPUSCULAR VOLUME (MCV). A measure of the average volume of a red blood cell.

MEASLES. An acute and highly contagious viral disease that occurs primarily in children marked by distinct red spots followed by a rash.

MEASLES ENCEPHALITIS. A serious complication of measles occurring in about one out of every 1,000 cases, causing headache, drowsiness, and vomiting seven to ten days after the rash appears. Seizures and coma can follow, which may lead to retardation and death.

MEATUS. A general term for an opening or passageway in the body.

MECHANICAL VALVE. An artificial device used to replace the patient's heart valve. They include three types: ball valve, disk valve, and bileaflet valve.

MECHANICAL VENTILATION. The process of maintaining respiration in a patient who cannot breathe naturally by means of a respiratory device.

MECONIUM. The first feces passed by the newborn. If passed before birth, the fetus can inhale this material, causing medical complications.

MECONIUM ASPIRATION SYNDROME. Breathing in of meconium (a newborn's first stool) by a fetus or newborn, which can block air passages and interfere with lung expansion.

MEDIA. Substance which contains all the nutrients necessary for bacteria to grow in a culture.

MEDIAN NERVE. A nerve that runs through the wrist and into the hand. It provides sensation and some movement to the hand, the thumb, the index finger, the middle finger, and half of the ring finger.

MEDIASTINOSCOPE. A thin hollow tube for performing mediastinoscopy.

MEDIASTINOSCOPY. A procedure that allows the physician to see the organs in the mediastinal space using a thin, lighted, hollow tube (a mediastinoscope).

MEDIASTINOTOMY. Surgical incision into the mediastinum.

MEDIASTINUM. The area between the lungs, bounded by the spine, breastbone, and diaphragm.

MEDICAID. The federally funded program in the United States for state-operated programs that provide medical assistance to permanently disabled patients and to low-income people. Medicaid is the medical assistance provided in Title XIX of the Social Security Act.

MEDICAL AGENT. A designated representative for the patient who, in advance, is legally empowered to carry out their wishes with respect to medial care.

MEDICAL EXAMINER (ME). A public officer charged with the duty of investigating deaths or injuries that occur under suspicious circumstances and to perform postmortem examinations. In most jurisdictions in the United States, the ME is required to hold a medical degree (MD or DO), but in some areas, he or she need not have any special medical or scientific training.

MEDICAL SURROGATE. Another name for a medical agent or person legally designated to represent the patient with medical providers.

MEDICAL TELEMETRY. The transmission of medical data.

MEDICAL TOURISM. The practice of seeking health care (most often elective surgical procedures) outside one's own country. It should not be confused with travel medicine, which is a medical specialty that deals with the prevention of disease and the treatment of medical emergencies in international travelers.

MEDICARE. The federally funded national health insurance program, provided for by Title XVIII of the Social Security Act in the United States for all people over the age of 65.

MEDICARE ADVANTAGE PLANS. Medicare Part C; private managed-care plans that include all Medicare Part A and Part B benefits and usually some additional benefits.

MEDICARE PART D. An optional, subsidized, outpatient prescription drug benefit provided through a private insurer.

MEDIONECROSIS. Death of the tunica, which is the middle layer of tissues in a vessel.

MEDITATION. Technique of calming the mind.

MEDITERRANEAN DIET. A diet based on the eating habits of people living in the Mediterranean region. It emphasizes fruits, vegetables, nuts, grilled seafood and poultry, olive oil, and a glass of red wine daily. There is little to no red meat, butter, or eggs.

MEDULLA OBLONGATA. The lowest section of the brainstem, located next to the spinal cord. The medulla is the site of important cardiac and respiratory regulatory centers.

MEDULLARY THYROID CANCER (MTC). A slow-growing tumor associated with MEN.

MEFLOQUINE. An antimalarial drug that was developed by the United States Army in the early 1980s. Today, malaria resistance to this drug has become a problem in some parts of Asia (especially Thailand and Cambodia).

WWW.BOOKBAZ.IR

MEGACOLON. Abnormally large colon associated with some chronic intestine disorders.

MEGADOSE. A very large dose of a vitamin, taken by some people as a form of self-medication.

MEGAKARYOCYTE. A large bone marrow cell with a lobed nucleus that is the precursor cell of blood platelets.

MEGALOBLAST. A large erythroblast (a red marrow cell that synthesizes hemoglobin).

MEGALOBLASTIC ANEMIA. A type of anemia characterized by abnormally large red blood cells; usually caused by folate or vitamin B_{12} deficiencies.

MEIBOMIAN GLAND. Oil-producing glands in the eyelids that open near the eyelid margins.

MELANIN. A pigment that is responsible for the color of hair, skin and eyes. Melanin also protects the body by absorbing ultraviolet light.

MELANOCYTE. An epidermal skin cell that produces melanin.

MELANOMA. A rapidly spreading and deadly form of cancer that usually occurs on the skin.

MELASMA. A dark mask-like discoloration that covers the cheeks and bridge of the nose. Also called "the mask of pregnancy."

MELATONIN. A hormone that helps to regulate circadian rhythms.

MEMBRANE OXYGENATOR. The artificial lung that adds oxygen and removes carbon dioxide.

MENADIONE. A synthetic form of vitamin K. It is sometimes called vitamin K_3.

MENARCHE. The medical term for a girl's first menstrual period.

MENDELIAN INHERITANCE. An inheritance pattern for autosomal gene pairs. The genetic trait displayed results from one parent's gene dominating over the gene inherited from the other parent.

MENGHINI NEEDLE/JAMSHEDI NEEDLE. Special needles used to obtain a sample of liver tissue by aspiration.

MÉNIÈRE'S DISEASE. A disorder of the membranous labyrinth of the inner ear that is marked by recurrent attacks of dizziness, tinnitus, and deafness—also called Ménière's syndrome. It is named after Prosper Ménière (1799–1862), a French physician who was among the first people to study diseases of the ear, nose, and throat.

MENINGES. The membranes that cover the brain and spinal cord.

MENINGITIS. Inflammation of tissues that surround the brain and spinal cord.

MENISCUS. One of two crescent-shaped pieces of cartilage attached to the upper surface of the tibia. The menisci act as shock absorbers within the knee joint.

MENISCUS (MENISCAL). A fibrous, cartilaginous structure that divides a joint cavity.

MENOPAUSE. The stage in a woman's life when menstruation stops.

MENORRHAGIA. Excessively heavy menstrual flow with cycles of normal length. It is also called hypermenorrhea.

MENTASTICS. The active phase of Trager therapy. Mentastics are a form of movement reeducation in which clients learn to reexperience movement as pleasurable and positive.

MEQ/L. Abbreviation for milliequivalents per liter. Some medical tests results are reported in mEq/L.

MERCURIC CHLORIDE; MERCURY(II) CHLORIDE; $HGCL_2$. A poisonous crystalline form of inorganic mercury that is used as a disinfectant and fungicide.

MERIDIAN. A section of a sphere. For example, longitude or latitude on the globe. Or, on a clock, a section going through 12:00-6:00 or 3:00-9:00, etc.

MERS-COV. The coronavirus that causes Middle East respiratory syndrome.

MESENTERIC ADENITIS. Inflammation of the lymph nodes that serve the small intestine, with symptoms similar to appendicitis.

MESENTERY. The membranes, or one of the membranes (consisting of a fold of the peritoneum and enclosed tissues), that connect the intestines and their appendages with the dorsal wall of the abdominal cavity.

MESOSALPINX. A ligament connected to the fallopian tube.

MESOTHELIOMA. A tumor derived from mesothelial tissue such as the lining of the lungs, thorax, or perineum.

MESOTHELIUM. A membrane/sac that protects the body's major internal organs and allows them freedom of movement (for example, lung contractions). The mesothelium is comprised of several regions, including

the abdominal cavity (peritoneum), the chest cavity (pleura), and pericardium (heart).

METABOLIC. Refers to the chemical processes of an organ or organism.

METABOLIC ACTIVITY. The sum of the chemical processes in the body that are necessary to maintain life.

METABOLIC BONE DISEASE. Weakening of bones due to a deficiency of certain minerals, especially calcium.

METABOLIC EQUIVALENT OF TASK (MET). The energy cost of a physical activity, measured as a multiple of the resting metabolic rate, which is defined as 3.5 milliliters of oxygen consumed per kilogram (kg) of body weight per minute, equivalent to 1 kilocalorie per kg per hour.

METABOLIC FUNCTION. Those processes necessary for the maintenance of a living organism.

METABOLIC PATHWAY. A sequence of chemical reactions that lead from some precursor to a product, where the product of each step in the series is the starting material for the next step.

METABOLIC SYNDROME. A syndrome characterized by at least three factors—such as high blood pressure, abdominal obesity, high triglyceride levels, low HDL ("good") cholesterol levels, and high fasting blood sugar levels and insulin resistance—that are linked to increased risk for heart disease and type 2 diabetes.

METABOLISM. The sum of all chemical reactions that occur in the body resulting in growth, transformation of foodstuffs into energy, waste elimination, and other bodily functions.

METABOLITE. In medicine, any substance produced during digestion or the breakdown of a drug in the body.

METACERCARIA (PLURAL, METACERCARIAE). The encysted stage of a fluke larva that produces infection in human beings.

METASTASIS. The spread of cancer from its initial site to another part of the body.

METASTATIC CANCER. A cancer that has spread to an organ or tissue from a primary cancer located elsewhere in the body.

METERED-DOSE INHALER (MDI). A device that delivers a measured dose of asthma medication directly into the lungs.

METHAMPHETAMINE (METH, METHADRINE, "SPEED"). A highly addictive medication that is used to treat attention deficit disorder and obesity, but is widely abused as a stimulant.

METHEMOGLOBIN. A compound formed from hemoglobin by oxidation.

METHICILLIN-RESISTANT *STAPHYLOCOCCUS AUREUS* (MRSA). A bacteria that is resistant to many antibiotics.

METHOTREXATE. The most widely used disease-modifying antirheumatic drug.

METHYLATION TESTING. DNA testing that detects if a gene is active or imprinted.

METHYLENE BLUE. A dye that is used to stain the blood cells for the reticulocyte count.

METHYLMERCURY. Any of various toxic compounds containing the organic grouping CH_3Hg. These compounds occur as industrial byproducts and pesticide residues, accumulate in fish and other organisms, especially those high on the food chain, and are rapidly absorbed through the human intestine to cause neurological disorders such as Minamata disease.

METRONIDAZOLE. An anti-infective agent regarded as the best available drug for treating trichomoniasis. It is sold under the trade names Flagyl and MetroGel.

M-HEALTH. A term used for the practice of telehealth by mobile devices. It is also spelled mHealth.

MIASM. In homeopathy, an inherited weakness or predisposition to disease. The syphilitic miasm is considered to be one of the most powerful.

MICROAMPERE (UA). A unit of current equal to one millionth of an ampere.

MICROANGIOPATHIC. Pertaining to disorders of the small blood vessels.

MICROBE. A microorganism, especially a bacterium, that causes disease.

MICROBIOTA. The collection of microorganisms that live in the human body (or another ecological niche) taken as a whole.

MICROCALCIFICATIONS. Tiny flecks that are too small to be felt. They are important markers of cancer that show up on ultrasound and mammogram.

MICROCEPHALY. An abnormally small head.

MICROCIRCULATION. The passage of blood in the smallest blood vessels of the body, such as the capillaries in the hand and fingers.

MICROCYTIC. A descriptive term applied to a smaller than normal red blood cell.

WWW.BOOKBAZ.IR

MICRODISKECTOMY. Microdecompression; minimally invasive spinal surgery (MISS) for disk removal.

MICROEMBOLI. Small blot clots in the bloodstream.

MICROFILARIAE. The larvae and infective form of filarial worms.

MICROFLORA. The bacterial population in the intestine.

MICROGRAVITY. Low-gravity environment, as occurs in orbit.

MICRONUTRIENT. A nutrient, such as a vitamin, that is required in minute amounts in the diet for growth and health.

MICROORGANISM. An organism that is too small to be seen with the naked eye.

MICROSPORIDA. A type of parasitic protozoa.

MICROSURGERY. Surgery on small body structures or cells performed with the aid of a microscope and other specialized instruments.

MICROTUBULES. Slender, elongated anatomical channels in worms.

MIDDLE EAR. The small cavity between the eardrum and the oval window that houses the three tiny bones of hearing.

MIDDLE MEATUS. A curved passage in each nasal cavity located below the middle nasal concha and extending along the entire superior border of the inferior nasal concha.

MIDDLE TURBINATE. The lower of two thin bony processes on the ethmoid bone on the lateral wall of each nasal fossa that separates the superior and middle meatus of the nose.

MIGRAINE. A throbbing headache that usually affects only one side of the head. Nausea, vomiting, increased sensitivity to light, and other symptoms often accompany migraine.

MIGRAINE NEURALGIA. A variant of migraine pain, also called cluster headache, in which severe attacks of pain affect the eye and forehead on one side of the face.

MIGRAINE WITH AURA (MWA). Migraine headache that is preceded by an aura.

MIGRAINE WITHOUT AURA (MWOA). Migraine headache that is not preceded by an aura.

MILD COGNITIVE IMPAIRMENT (MCI). A transitional phase of memory loss in older people that precedes dementia or AD.

MILIA. Small bumps on the skin that occur when sweat glands are clogged.

MILIARY TUBERCULOSIS. The form of TB in which the bacillus spreads through all body tissues and organs, producing many thousands of tiny tubercular lesions. Miliary TB is often fatal unless promptly treated.

MILK-ALKALI SYNDROME. Elevated blood calcium levels and alkalosis caused by excessive intake of milk and alkalis. Usually occurs in the treatment of peptic ulcer.

MINERAL. An inorganic substance found in the earth that is necessary in small quantities for the body to maintain a health. Examples: zinc, copper, iron.

MINERALIZATION. The process by which the body uses minerals to build bone structure.

MINIGRAFT OR MICROGRAFT. Transplantation of a small number of hair follicles, as few as one to three hairs, into a transplant site.

MINIMUM ERYTHEMA DOSE. The minimum amount of UVB that produces redness 24 hours after exposure. It is the starting dose for UVB light treatments.

MINIMUM PHOTOTOXIC DOSE. The dose of UVA that produces uniform redness 72 hours after ingesting a psoralen compound. It becomes the starting dose for PUVA treatment.

MIOTIC. A drug that causes pupils to contract.

MIRACIDIUM. The form of the schistosome worm that infects freshwater snails.

MISCARRIAGE. Spontaneous pregnancy loss.

MISO. A fermented paste made from soybeans, salt, and rice or barley, used to flavor soups and sauces in Asian cooking.

MISPROSTOL. A drug used in combination with mifepristone to cause uterine contractions that expel the contents of the uterus.

MITE. An insect parasite belonging to the order Acarina. The organism that causes scabies is a mite.

MITOCHONDRIA. The organelles in cells that produce energy through respiration.

MITRAL STENOSIS. Narrowing or constricting of the mitral valve, which separates the left atrium from the left ventricle.

MITRAL VALVE. The bicuspid valve that lies between the left atrium and left ventricle of the heart.

MITRAL VALVE LEAFLETS. The mitral valve is made up of two valve leaflets (the anteromedial leaflet and the posterolateral leaflet) and a ring around the valve, known as the mitral valve annulus. The orientation of the two leaflets resembles a bishop's miter, which is where the valve receives its name.

MITRAL VALVE PROLAPSE. A heart defect in which one of the valves of the heart (which normally controls blood flow) becomes floppy. Mitral valve prolapse may be detected as a heart murmur but there are usually no symptoms.

MIXED MANIA. A mental state in which symptoms of both depression and mania occur simultaneously.

MOBILIZATION. Making movable, restoring the power of motion in a joint. Movement which increases joint mobility.

MODALITIES. The factors and circumstances that cause a patient's symptoms to improve or worsen.

MODIFIED RADICAL MASTECTOMY. Total mastectomy with axillary lymph node dissection, but with preservation of the chest muscles.

MOHS SURGERY. A form of microscopically controlled surgery that allows for the precise removal of cancerous tissue. It is commonly used to treat various types of skin cancer, particularly in areas of the body where preserving as much tissue as possible is essential. Mohs surgery is also known as micrographic surgery.

MOHS' MICROGRAPHIC SURGERY. A surgical technique in which successive rings of skin tissue are removed and examined under a microscope to ensure that no cancer is left.

MOLARS. The teeth behind the primary canines or the permanent premolars, with large crowns and broad chewing surfaces for grinding food.

MOLECULAR. Composed of molecules, or studied and addressed at individual and detailed levels. In medicine, this means understanding how genes, proteins, and other molecules on cells cause or affect disease.

MOLLUSCUM CONTAGIOSUM. A disease of the skin and mucous membranes, caused by a poxvirus and found all over the world.

MONOAMINE OXIDASE (MAO) INHIBITORS. A group of anti-depressant drugs.

MONOCHORIONIC TWINS. Twins that share a single placenta.

MONOCLONAL. Identical cells or proteins; cells (clones) derived from a single, genetically distinct cell, or proteins produced by these cells.

MONOCLONAL ANTIBODY. An antibody produced by the identical offspring of a single cloned antibody-producing cell.

MONOCLONAL GAMMOPATHY OF UNDETERMINED SIGNIFICANCE (MGUS). Common condition in which M-protein is present, but there are no tumors or other symptoms of disease.

MONOCYTE. A type of white blood cell produced in bone marrow.

MONOGAMY. Being married to only one person or having only one sexual partner at a time.

MONONUCLEAR PHAGOCYTE. A type of cell of the human immune system that ingests bacteria, viruses, and other foreign matter, thus removing potentially harmful substances from the bloodstream. These substances are usually then digested within the phagocyte.

MONONUCLEOSIS. An infection which causes swelling of lymph nodes, spleen, and liver, usually accompanied by extremely sore throat, fever, headache, and intense long-lasting fatigue.

MONOSACCHARIDE. The simplest form of sugar. Monosaccharides combine to form disaccharides and complex carbohydrates.

MONOUNSATURATED FAT. A fat or fatty acid with only one double-bonded carbon atom in its molecule. The most common monounsaturated fats are palmitoleic acid and oleic acid. They are found naturally in such foods as nuts and avocados; oleic acid is the main component of olive oil.

MONS PUBIS. The fatty tissue over the area where the pubic bones meet.

MONSEL'S SOLUTION. A solution used to stop bleeding.

MONTELUKAST. An inhibitor that prevents leukotrienes from binding to cell receptors; taken over time, montelukast can reduce or prevent symptoms of asthma and allergies.

MOOD DISORDER. A collection of disorders that includes major depression and bipolar disorder. They are all characterized by major disruptions in patients' moods and emotions.

MORBID. Unwholesome or bad for health.

WWW.BOOKBAZ.IR

MORBIDITY. Refers to an illness or disease condition. In statistics it refers to the rate at which a disease occurs.

MORBIDLY OBESE. Defines a person who is 100 lb (45 kg) (or more than 50%) overweight and has a body mass index above 40.

MORCELLATION. The division of tissue or tumors into smaller pieces.

MORO REFLEX. A reflex startle reaction in infants; the arms and legs move away from the body and to the side and are then drawn together.

MORPHEA. The most common form of localized scleroderma.

MORPHINE. The naturally occurring opioid in the opium poppy, *Papaver somniferum*. It is a powerful narcotic analgesic, and its primary clinical use is in the management of moderately severe to severe pain. After heroin, morphine has the greatest potential for addiction of all narcotic analgesics.

MORPHOLOGY. The form or structure of an organism, as contrasted with its functioning.

MORTALITY. Mortality means death. In statistics it refers to the rate at which death occurs in a population for a particular disease condition.

MOSAIC. A term referring to a genetic situation in which an individual's cells do not have the exact same composition of chromosomes. In Down syndrome, this may mean that some of the individual's cells have a normal 46 chromosomes, while other cells have an abnormal 47 chromosomes.

MOSAICISM. A genetic condition resulting from a mutation, crossing over, or nondisjunction of chromosomes during cell division, causing a variation in the number of chromosomes in the cells.

MOTHER TINCTURE. The first stage in the preparation of a homeopathic remedy, made by soaking a plant, animal, or mineral product in a solution of alcohol.

MOTILITY. Ability to move freely or spontaneously.

MOTION SICKNESS. Also called kinetosis; nausea and possibly vomiting induced by motion, such as travel by car, boat, or plane.

MOTOR. Of or pertaining to motion, the body apparatus involved in movement, or the brain functions that direct purposeful activity.

MOTOR NERVE. Motor or efferent nerve cells carry impulses from the brain to muscle or organ tissue.

MOTOR NEURON. Nerve cells within the central nervous system that carry nerve impulses controlling muscle movement.

MOTOR SKILLS. Controlled movement of muscle groups. Fine motor skills involve tasks that require dexterity of small muscles, such as buttoning a shirt. Tasks such as walking or throwing a ball involve the use of gross motor skills.

MOTOR UNIT ACTION POTENTIALS. Spikes of electrical activity recorded during an EMG that reflect the number of motor units (motor neurons and the muscle fibers they transmit signals to) activated when the patient voluntarily contracts a muscle.

MOURNING. The public expression of bereavement; it may include funerals and other rituals, special clothing, and symbolic gestures.

MOUSSE OIL. Crude oil that has emulsified or weathered, mixed with dispersants, water, and marine material to form a spongy, light brown, mousse-like material.

MOUTH GUARD. A plastic device that protects the upper teeth from injury during athletic events.

MOXIBUSTION. An acupuncture technique that burns the herb moxa or mugwort.

M-PROTEIN. Monoclonal or myeloma protein; paraprotein; abnormal antibody found in large amounts in the blood and urine of individuals with multiple myeloma.

MUCIN. A protein in saliva that combines with sugars in the mouth to form plaque.

MUCINOUS (COLLOID) CARCINOMA. A type of cancer that accounts for 1–2% of breast cancers. Resembles medullary carcinoma in ultrasound and mammogram, but usually affects older women.

MUCOCILIARY. Involving cilia of the mucous membranes of the respiratory system.

MUCOCILIARY ESCALATOR. The coordinated action of tiny projections on the surfaces of cells lining the respiratory tract, which moves mucus up and out of the lungs.

MUCOCUTANEOUS LYMPH NODE SYNDROME (MLNS). Mucocutaneous lymph node syndrome, another name for Kawasaki syndrome. The name comes from the key symptoms of the disease, which involve the mucous membranes of the mouth and throat, the skin, and the lymph nodes.

MUCOLYTIC. An agent that dissolves or destroys mucin, the chief component of mucus.

MUCOPOLYSACCHARIDE. A complex molecule made of smaller sugar molecules strung together to form a chain. Found in mucous secretions and intercellular spaces.

MUCOSA. The mucous membrane, or the thin layer which lines body cavities and passages.

MUCOSAL. Refers to tissues that produce mucus, such as the digestive, genital, and urinary tracts.

MUCOUS. Thick fluid produced by the moist membranes that line many body cavities and structures.

MUCOUS MEMBRANE. A membrane rich in mucous glands that lines body passages and cavities communicating directly or indirectly with the exterior of the body (as for example, the alimentary, respiratory, and genitourinary tracts). Mucous membranes functions in protection, support, nutrient absorption, and secretion of mucus, enzymes, and salts.

MUCUS. A thin, slippery film secreted by the mucous membranes and glands.

MULTIDRUG-RESISTANT (MDR). Bacteria that are resistant to one or more classes of antimicrobial agents and usually are resistant to all but one or two commercially available antimicrobial agents.

MULTI-FETAL PREGNANCY. A pregnancy of two or more fetuses.

MULTIFOCAL. Having many focal points. In progressive multifocal leukoencephalopathy, it means that damage caused by the disease occurs at multiple sites.

MULTIFOCAL. More than one tumor present.

MULTI-INFARCT DEMENTIA. Major neurocognitive disorder caused by damage to brain tissue resulting from a series of blood clots or clogs in the blood vessels. It is also called vascular major neurocognitive disorder.

MULTINODULAR GOITER. A condition in which benign lumps of tissue (nodules) form within the thyroid gland and cause it to secrete too much thyroid hormone. It is also called Plummer's disease.

MULTIPLE CHEMICAL SENSITIVITY. A condition characterized by severe and crippling allergic reactions to commonly used substances, particularly chemicals. Also called environmental illness.

MULTIPLE ENDOCRINE NEOPLASIA. Abnormal tissue growth on one or more of the endocrine (hormone-secreting) glands.

MULTIPLE ENDOCRINE NEOPLASIA TYPE 1 (MEN-1). An inherited condition marked by multiple malignancies of the pituitary gland, parathyroid gland, and islet cells of the pancreas. About half of MEN-1 patients with pancreatic islet cell tumors will have gastrinomas, gastrin-producing tumors that lead to ulcer disease.

MULTIPLE MYELOMA. A malignancy (cancer) of a certain kind of white blood cell, called a plasma cell.

MULTIPLE PERSONALITY DISORDER (MPD). An older term for dissociative identity disorder (DID).

MULTIPLE SCLEROSIS. A disease that destroys the covering (myelin sheath) of nerve fibers of the brain and spinal cord.

MULTITASKING. Performing multiple duties or taking on multiple responsibilities and roles simultaneously.

MUMPS. An acute and highly contagious viral illness that usually occurs in childhood.

MUNCHAUSEN BY PROXY. A factitious disorder in which a parent or other caregiver may falsify a child's medical history or take other action to make a healthy child appear sick.

MUNCHAUSEN SYNDROME. A factitious disorder in which the patient's symptoms are dramatized and exaggerated.

MURINE TYPHUS. A form of typhus that is transmitted by fleas carried by rats. It is also called endemic typhus, and should be distinguished from epidemic typhus, which is carried by body lice.

MURMUR. An abnormal heart sound that can reflect a valve dysfunction.

MUSCLE TONE. Also termed tonus; the normal state of balanced tension in the tissues of the body, especially the muscles.

MUSCULAR DYSTROPHY. A group of inherited diseases characterized by progressive wasting of the muscles.

MUTATE. Undergo a spontaneous change in the make-up of genes or chromosomes.

MUTATION. Any change in the hereditary material of genes.

MUTISM. The inability or refusal to speak.

MYALGIA. Muscular pain or tenderness, typically of a diffuse and/or nonspecific nature.

WWW.BOOKBAZ.IR

MYALGIC ENCEPHALOMYELITIS. An older name for chronic fatigue syndrome; encephalomyelitis refers to inflammation of the brain and spinal cord.

MYASTHENIA GRAVIS. A muscle weakness that occurs because the body makes antibodies to the natural chemical that facilitates transmission of impulses between the nerve and the muscle.

MYCOBACTERIA. A group of bacteria that includes *Mycobacterium tuberculosis*, the bacterium that causes tuberculosis, and other forms that cause related illnesses.

MYCOLOGY. The branch of biology that deals with the systematic study of fungi.

MYCOPLASMA. A type of free-living microorganism that has no cell wall. Mycoplasmas cause some varieties of pneumonia and urinary tract infections that stimulate the body to produce cold agglutinins.

MYCOPLASMA PNEUMONIA. An incomplete bacterium that infects the lung.

MYCOSIS. The medical term for a fungal infection.

MYCOSIS FUNGOIDES. The most common type of cutaneous T-cell lymphoma. This low-grade lymphoma primarily affects the skin. Generally, it has a slow course and often remains confined to the skin. Over time, in about 10% of cases, it can progress to the lymph nodes and internal organs.

MYDRIATIC. Causing dilation or widening of the pupil of the eye.

MYELIN. The substance that is wrapped around nerves. Myelin is responsible for speed and efficiency of impulses traveling through those nerves. When the myelin sheath is damaged, nerve communication is disrupted.

MYELODYSPLASIA. Also called myelodysplastic syndrome, it is a condition in which the bone marrow does not function normally and can affect the various types of blood cells produced in the bone marrow. Often referred to as a preleukemia and may progress and become acute leukemia.

MYELOFIBROSIS. An anemic condition in which bone marrow cells are abnormal or defective and become fibrotic.

MYELOGRAM. An x-ray exam of the spinal cord, nerves, and other tissues within the spinal cord that are highlighted by injected contrast dye.

MYELOGRAPHY. An imaging procedure involving the injection of a radioactive dye into the fluid surrounding the spine. A myelography can be used to detect herniated disks, nerve root damage, and other problems affecting the cervical spine.

MYELOMA (MULTIPLE MYELOMA). A tumor of plasma cells that originates in bone marrow and usually spreads to more than one bone.

MYELOMENINGOCELES (MMC). A protrusion in the vertebral column containing spinal cord and meninges.

MYELOPATHY. A disorder in which the tissue of the spinal cord is diseased or damaged.

MYELOPROLIFERATIVE DISORDER. A disorder in which the bone marrow produces too many cells too rapidly.

MYELOSUPPRESSIVE THERAPY. Any form of treatment that is aimed at slowing down the rate of blood cell production.

MYOCARDIAL INFARCTION. Commonly known as a heart attack, a myocardial infarction is an episode in which some of the heart's blood supply is severely cut off or restricted, causing the heart muscle to suffer and die from lack of oxygen.

MYOCARDITIS. Inflammation of the heart muscle.

MYOCARDIUM. The thick middle layer of the heart that forms the bulk of the heart wall and contracts as the organ beats.

MYOCLONIC. A rapid, involuntary muscle contraction, particularly near the eye.

MYOCLONUS. Jerking, involuntary movements of the arms and legs. These may occur normally during sleep.

MYOFASCIAL. The fibrous tissue that encloses and separates layers of muscles.

MYOGLOBIN. A protein that holds oxygen in heart and skeletal muscle. It rises after damage to either of these muscle types.

MYOGLOBINURIA. Reddish urine caused by excretion of myoglobin, a breakdown product of muscle.

MYOMA. These are benign (non-malignant) tumors of the uterus.

MYONECROSIS. The destruction or death of muscle tissue.

MYOPATHY. A disorder that causes weakening of muscles.

MYOPIA. Nearsightedness. People with myopia cannot see distant objects clearly.

MYOTONIC DYSTROPHY. A genetic defect resulting in abnormal muscle function.

MYRINGOTOMY. A surgical procedure performed to drain an infected middle ear. A newer type of myringotomy uses a laser instead of a scalpel.

MYXEDEMA. Hypothyroidism, characterized by thick, puffy features, an enlarged tongue, and lack of emotion.

N

NAIL BED. The layer of tissue underneath the nail.

NALTREXONE. A medication originally developed to treat addiction to heroin or morphine that is also used to treat alcoholism. It works by reducing the craving for alcohol rather than by producing vomiting or other unpleasant reactions.

NANOMETER. A measurement of length equal to 10^{-9} meters, or one billionth of a meter. It is used as a unit of measurement for light waves.

NARCISSISTIC. Relating to a personality disorder in which an individual overestimates his or her own abilities or appearance, such as an extraordinary ability to win at gambling.

NARCOLEPSY. A lifelong sleep disorder marked by four symptoms: sudden brief sleep attacks, cataplexy, temporary paralysis, and hallucinations. The hallucinations are associated with falling asleep or the transition from sleeping to waking.

NARCOTIC. A drug derived from opium or compounds similar to opium. Such drugs are potent pain relievers and can affect mood and behavior. Long-term use of narcotics can lead to dependence and tolerance.

NASAL CONCHA. Any of three thin bony plates on the lateral wall of the nasal fossa on each side with or without their covering of mucous membrane.

NASAL POLYPS. Drop-shaped overgrowths of the nasal membranes.

NASAL SCRAPING. Pathological material obtained for clinical study by scratching the inner surface of the nose with a clinical instrument.

NASAL SEPTUM. The cartilage that divides the nose in half.

NASOGASTRIC. Tube inserted through the nasal passages into the stomach.

NASOGASTRIC TUBE. A tube placed through the nose into the stomach.

NASOLACRIMAL DUCT. The tube that carries the tears from the lacrimal sac to the nose.

NASOPHARYNGEAL. Referring to the passage connecting the nasal cavity behind the nose to the top of the throat behind the soft palate.

NASOPHARYNGOSCOPY. A diagnostic procedure that examines the nasal passageways and pharynx with an instrument outfitted with an optical system.

NASOPHARYNX. The part of the airway into which the nose leads.

NATURAL KILLER (NK) CELL. A large-celled lymphocyte that functions as part of the innate immune system to respond to cells infected by viruses and tumor cells.

NATUROPATHIC PHYSICIANS. Physicians specializing in the treatment of disease using a variety of natural methods and plant-based medicines.

NATUROPATHY. A type of alternative medicine maintaining that humans have an innate vital force that can be fostered by noninvasive treatments, encouragement of natural healing, and minimal use of surgery and drugs.

NAUSEA. A feeling of unease or discomfort in the upper stomach associated with an involuntary urge to vomit. It often precedes actual vomiting but may also occur without vomiting.

NAXALONE. An opioid antagonist that is used to counteract narcotic overdoses and to treat narcotic addiction and withdrawal.

NEAR-INFRARED SPECTROSCOPY (NIRS). A diagnostic technique for measuring oxygen saturation in tissues.

NEARSIGHTEDNESS. A condition in which one or both eyes cannot focus normally, causing objects at a distance to appear blurred and indistinct. Also called myopia.

NEBULIZER. A device for converting liquid asthma medication into a fine mist that can be inhaled directly into the lungs through a mouthpiece or facemask.

NECROSIS. Abnormal death of cells, potentially caused by disease or infection.

NECROTIC. Abnormal death of cells, potentially caused by disease or infection.

WWW.BOOKBAZ.IR

NECROTIZING ENTEROCOLITIS (NEC). A condition in which part of the intestines are destroyed as a result of bacterial infection.

NECROTIZING FASCIITIS. A destructive infection which follows severe cellulitis and involves the deep skin and underlying tissues.

NECROTIZING PNEUMONIA. Pneumonia that causes the death of lung tissue. It often precedes the development of lung abscess.

NEEDLE BIOPSY. The procedure of using a large hollow needle to obtain a sample of intact tissue.

NEGATIVE SYMPTOMS. Symptoms of schizophrenia characterized by the absence or elimination of certain behaviors.

NEGATIVISM. Behavior characterized by resistance, opposition, and refusal to cooperate with requests, even the most reasonable ones.

NEISSERIA GONORRHOEAE. The bacterium that causes gonorrhea.

NEMATODE. A parasitic roundworm with a long, cylindrical body.

NEOADJUVANT CHEMOTHERAPY. Treatment of the tumor with drugs before surgery to reduce the size of the tumor.

NEOADJUVANT THERAPY. The administration of chemotherapy, hormone therapy, or radiation therapy before surgery. It is usually done to shrink the volume of the tumor.

NEOBLADDER. A term that refers to the creation of a reservoir for urine made from intestinal tissue that allows for evacuation.

NEONATAL. Referring to the period shortly after birth.

NEONATAL JAUNDICE. A disorder in newborns where the liver is too premature to conjugate bilirubin, which builds up in the blood.

NEONATE. A term referring to the newborn infant, from birth until one month of age.

NEONATOLOGIST. A physician who specializes in problems of newborn infants.

NEOPLASIA. Abnormal growth of cells, which may lead to a neoplasm, or tumor.

NEOPLASM. An abnormal formation of tissue; for example, a tumor.

NEOVASCULARIZATION. Growth of new blood vessels.

NEPHRECTOMY. A medical procedure in which the kidney is surgically removed.

NEPHRITIS. Inflammation of the kidneys.

NEPHROLOGIST. A doctor who specializes in the diseases and disorders of the kidneys.

NEPHRON. The smallest functional unit of the kidney involved in the removal of waste products and excess water from the blood.

NEPHROSCOPE. An instrument made of a light source in a tube. The tube is inserted into the kidney through an incision in the back and used to locate kidney stones. The stones are broken up with high frequency sound waves and removed by suction through the scope.

NEPHROTIC SYNDROME. A collection of symptoms that result from damage to the filtering units of the kidney (glomeruli), causing severe loss of protein from the blood into the urine.

NEPHROTOXIC. Toxic, or damaging, to the kidney.

NEPHROTOXICITY. The quality or state of being toxic to kidney cells.

NEPHROTOXIN. Substance that is poisonous to the kidneys.

NERVE BIOPSY. A medical test in which a small portion of a damaged nerve is surgically removed and examined under a microscope.

NERVE CONDUCTION. The speed and strength of a signal being transmitted by nerve cells. Testing these factors can reveal the nature of nerve injury, such as damage to nerve cells or to the protective myelin sheath.

NERVE CONDUCTION VELOCITY TEST. A test that measures the time it takes a nerve impulse to travel a specific distance over the nerve after electronic stimulation.

NERVE GROWTH FACTOR. A protein resembling insulin that affects growth and maintenance of nerve cells.

NERVOUS SYSTEM. The complete network of nerves, sense organs, and brain in the body.

NERVOUS TIC. A repetitive, involuntary action, such as the twitching of a muscle or repeated blinking.

NEUCHAL TRANSLUCENCY. A pocket of fluid at the back of an embryo's neck visible via ultrasound that,

when thickened, may indicate the infant will be born with a congenital heart defect.

NEURAL TUBE DEFECT (NTD). Defective neural tube, the narrow sheath that closes to form the brain and spinal cord of the embryo.

NEURAL TUBE DEFICIT. A defect in an embryo's neural tube, which develops into the spinal cord and brain.

NEURALGIA. Pain extending along one or more nerves.

NEURALLY MEDIATED HYPOTENSION. A rapid fall in blood pressure that causes dizziness, blurred vision, and fainting; it is often followed by prolonged fatigue.

NEURASTHENIA. A term coined in the late nineteenth century to refer to a condition of chronic mental and physical weakness and fatigue.

NEURITIS. An inflammation of the nerves.

NEUROBLAST. An embryonic nerve cell that differentiates into a neuron.

NEUROBLAST CELLS. Cells produced by the fetus which mature into nerve cells and adrenal medulla cells.

NEUROBLASTOMA. Neuroblastoma is a tumor of the adrenal glands or sympathetic nervous system. Neuroblastomas can range from being relatively harmless to highly malignant.

NEUROCYSTICERCOSIS. Parasitic infection caused by the presence of immature tapeworm larvae within the central nervous system.

NEURODEGENERATIVE. Relating to degeneration of nerve tissues.

NEURODERMATITIS. An itchy skin disease (also called lichen simplex chronicus) found in nervous, anxious people.

NEUROFIBRILLARY TANGLES. Accumulations of twisted protein fragments inside nerve cells in the brain that are diagnostic of AD.

NEUROFIBROMA. A soft tumor usually located on a nerve.

NEUROFIBROMATOSIS. A rare hereditary disease that involves the growth of lesions that may affect the spinal cord.

NEUROFIBROMATOSIS TYPE 2 (NF2). A hereditary condition associated with an increased risk of bilateral acoustic neuromas, other nerve cell tumors and cataracts.

NEUROGENIC. Referring to a disorder associated with damage to the central nervous system.

NEUROLEPTIC. Another name for older antipsychotic medications, such as haloperidol. The term does not apply to such newer atypical agents as clozapine (Clozaril).

NEUROLOGIC. Pertaining to the nervous system.

NEUROLOGICAL CONDITIONS. A condition that has its origin in some part of the patient's nervous system.

NEUROLOGICAL SYSTEM. The tissue that initiates and transmits nerve impulses, including the brain, spinal cord, and nerves.

NEUROLOGIST. A doctor who specializes in disorders of the brain and central nervous system.

NEUROMUSCULAR. The body system of nerves and muscles as they function together.

NEUROMUSCULAR JUNCTION. The site at which nerve impulses are transmitted to muscles.

NEURON. A unique type of cell found in the brain and body that is specialized to process and transmit information.

NEURON-SPECIFIC ENOLASE (NSE). An enzyme that may be elevated in tumors originating in neuroendocrine cells.

NEUROPATHY. A condition affecting the nerves supplying the arms and legs. Typically, the feet and hands are involved first. If sensory nerves are involved, numbness, tingling, and pain are prominent, and if motor nerves are involved, the patient experiences weakness.

NEUROPROTECTIVE. Conveying some form of protection to the nervous system from injury.

NEUROPSYCHOLOGICAL TEST. A test or assessment given to diagnose a brain disorder or disease.

NEUROPSYCHOLOGICAL TESTING. Tests used to evaluate patients who have experienced a traumatic brain injury, brain damage, or organic neurological problems (e.g., dementia). It may also be used to evaluate the progress of a patient who has undergone treatment or rehabilitation for a neurological injury or illness.

NEUROPSYCHOLOGIST. A clinical psychologist who specializes in assessing psychological status caused by a brain disorder.

NEUROSURGERY. Surgery performed on the brain.

WWW.BOOKBAZ.IR

NEUROSYPHILIS. Syphilis of the central nervous system.

NEUROTIC. Behavior characterized by neurosis, mental functional orders with symptoms such as anxiety, depression, compulsions, and phobias.

NEUROTOXIN. A substance that damages, destroys, or impairs the functioning of nerve tissue.

NEUROTRANSMISSION. When a neurotransmitter, or chemical agent released by a particular brain cell, travels across the synapse to act on the target cell to either inhibit or excite it.

NEUROTRANSMITTER. One of a group of chemicals secreted by a nerve cell (neuron) to carry a chemical message to another nerve cell, often as a way of transmitting a nerve impulse. Neurotransmitters include acetylcholine, dopamine, serotonin, and norepinephrine.

NEUTROPHIL. Segmented white blood cell normally comprising 50–70% of the total. The cytoplasm contains both primary and secondary granules that take up both acidic and basic dyes of the Wright stain. Neutrophils remove and kill bacteria by phagocytosis.

NEVUS. The medical term for any anomaly of the skin that is present at birth, including moles and birthmarks.

NIACINAMIDE. A form of niacin, which is usually used as a dietary supplement for people with insufficient niacin.

NICOTINE. A colorless, oily chemical found in tobacco that makes people physically dependent on smoking. It is poisonous in large doses.

NICOTINE REPLACEMENT THERAPY. A method of weaning a smoker from both nicotine and the oral fixation that accompanies a smoking habit by giving the smoker smaller and smaller doses of nicotine in the form of a patch or gum.

NIGHT GUARD. A removable, custom-fitted plastic appliance that fits between the upper and lower teeth to prevent them from grinding against each other.

NIMODIPINE (NIMOTOP). A calcium-channel blocker, that is, a drug that relaxes arterial smooth muscle by slowing the movement of calcium across cell walls.

NIPAH VIRUS (NIV). The virus that causes nipah disease and nipah encephalitis.

NIT. The egg sac laid by adult female lice.

NITROGEN NARCOSIS. Also called "rapture of the deep," the condition is caused by increased nitrogen pressure at depth and is characterized by symptoms similar to alcohol intoxication.

NITROPRUSSIDE. A compound that is used in laboratory tests to identify large amounts of cystine in urine samples.

NITROUS OXIDE. A colorless, sweet-smelling gas used by dentists for mild anesthesia. It is sometimes called laughing gas because it makes some people feel giddy or silly.

NOCICEPTOR. A nerve cell that is capable of sensing pain and transmitting a pain signal.

NOCTURIA. Excessive need to urinate at night.

NOCTURNAL ENURESIS. The medical term for bedwetting.

NOCTURNAL MYOCLONUS. A disorder in which the patient is awakened repeatedly during the night by cramps or twitches in the calf muscles. Nocturnal myoclonus is sometimes called periodic limb movement disorder (PLMD).

NODULAR GOITER. An enlargement of the thyroid (goiter) caused when groups of cells collect to form nodules.

NODULE. A hardened area or knot sometimes associated with infection.

NONDISJUNCTION. Nonseparation of a chromosome pair, during either meiosis or mitosis.

NON-HODGKIN'S LYMPHOMAS. Lymphomas characterized by different types of cancerous lymphatic cells, excluding those characterized by Hodgkin's disease.

NONINVASIVE. Describes any procedure that does not penetrate the body.

NONINVASIVE TUMORS. Tumors that have not penetrated the muscle wall and/or spread to other parts of the body.

NON-IONIZING RADIATION. Rays of energy that move in long, slow wave patterns and do not penetrate cells.

NONMELANOMA SKIN CANCER. A squamous cell carcinoma or basal cell carcinoma.

NON-MYELOABLATIVE ALLOGENEIC BONE MARROW TRANSPLANT. Also called "mini" bone marrow transplants. This type of bone marrow transplant involves receiving low-doses of chemotherapy and radiation

therapy, followed by the infusion of a donor's bone marrow or peripheral stem cells. The goal is to suppress the patient's own bone marrow with low-dose chemotherapy and radiation therapy to allow the donor's cells to engraft.

NON-NUCLEOSIDE REVERSE TRANSCRIPTASE INHIBITOR; NNRTI. An antiretroviral drug that inhibits the reverse transcriptase enzyme required for HIV replication.

NONOXYNOL-9. The chemical name of the organic compound most commonly used in contraceptive creams, foams, and jellies. It was also used in the manufacture of spermicide-treated condoms until 2005, but the use of such condoms is now discouraged.

NONPALPABLE. Unable to be detected through the sense of touch.

NONPHARMACOLOGICAL. Referring to therapy that does not involve drugs.

NONPROLIFERATIVE RETINOPATHY. Retinopathy without the growth of new blood vessels.

NON-RAPID EYE MOVEMENT (NREM) SLEEP. A type of sleep that differs from rapid eye movement (REM) sleep. The four stages of NREM sleep account for 75–80% of total sleeping time.

NONSPHEROCYTIC. Not sphere shaped. Often in inherited hemolytic anemias, red blood cells are sphere shaped. In nonspherocytic hemolytic anemias, red blood cells are not sphere shaped.

NONSTEROIDAL. Not containing steroids or cortisone. Usually refers to a class of drugs called Nonsteroidal Anti-Inflammatory Drugs (NSAIDs).

NONSTEROIDAL ANTI-INFLAMMATORY DRUGS (NSAIDS). Over-the-counter and prescription medications for reducing inflammation and pain.

NON-STRESS TEST. A record of the fetal heart rate in the absence of contractions (stress).

NONVERBAL LEARNING DISABILITY (NLD). A learning disability syndrome identified in 1989 that may overlap with some of the symptoms of Asperger syndrome.

NOREPINEPHRINE. A hormone released by nerve cells and the adrenal medulla that causes constriction of blood vessels. Norepinephrine also functions as a neurotransmitter.

NORMAL FLORA. The mixture of bacteria normally found at specific body sites.

NORMAL SALINE. Physiological saline; a solution of 0.9% sodium chloride, the approximate salt concentrate of blood and tissues.

NORMAL WEIGHT. A BMI of less than 25.0.

NORMAL WEIGHT OBESITY. A condition in which a person is within the normal weight range according to his or her BMI but has an unacceptably high percentage of body fat.

NORMOCHROMIC. A descriptive term applied to a red blood cell with a normal concentration of hemoglobin.

NORMOCYTIC. A descriptive term applied to a red blood cell of normal size.

NORMS. Normative or mean score for a particular age group.

NOROVIRUS. Norwalk virus; a large family of RNA viruses that is the most common cause of food poisoning.

NOSOCOMIAL. Originating or taking place in a hospital.

NOSOCOMIAL INFECTIONS. Infections that were not present before the patient came to a hospital but were acquired by a patient while in the hospital.

NOSODE. A homeopathic remedy made from microbes, pus, or other disease material. Syphilinum is a nosode made from a diluted solution of killed *T. pallidum*.

NOTCHING. A deformity of the surface of the ribs that is often associated with coarctation of the aorta.

NOTIFIABLE DISEASE. Any disease that is required by law to be reported to public health authorities. In the United States, the CDC maintains a list of nationally notifiable diseases monitored by the National Notifiable Diseases Surveillance System (NNDSS).

NPO. A term that means nothing by mouth. NPO refers to the time after which the patient is not allowed to eat or drink prior to a procedure or treatment.

NUCHAL CORD. The term used when the umbilical cord is looped around the fetus's neck in utero.

NUCHAL CYSTS. Small cysts in the fetus's neck that present in 1% of pregnancies.

NUCLEAR FAMILY. The basic family unit, consisting of father, mother, and their biological children.

NUCLEAR IMAGING. Method of producing images by detecting radiation from different parts of the body after a radioactive tracer material is administered.

WWW.BOOKBAZ.IR

NUCLEAR MEDICINE. A branch of medicine that makes use of radioisotopes (also called radionuclides) to evaluate the rate of radioactive decay in diagnosing and treating various diseases.

NUCLEAR SCANNING. Use of injected radioactive elements to analyze blood flow.

NUCLEIC ACID. A type of chemical used as a component for building DNA. The nucleic acids found in DNA are adenine, thymine, guanine, and cytosine.

NUCLEIC ACID AMPLIFICATION TEST (NAAT). A screening test for gonorrhea that detects bacterial DNA in a urine sample or cervical swab.

NUCLEIC ACIDS. The cellular molecules DNA and RNA that act as coded instructions for the production of proteins and are copied for transmission of inherited traits.

NUCLEOSIDE REVERSE TRANSCRIPTASE INHIBITOR (NRTI). An antiretroviral drug that interferes with the action of HIV reverse transcriptase inside infected cells, preventing the virus from replicating.

NUCLEOTIDES. Small molecules that form the building blocks of DNA and RNA, play important roles in cell metabolism, and participate in cell signaling.

NUCLEUS. The part of a cell that contains the DNA.

NUCLEUS ACCUMBENS. Abbreviated NAcc and also known as accumbens nucleus, is a part of the brain reward system, located in the limbic system, that processes information related to motivation and reward.

NUCLEUS PULPOSUS (NP). An elastic, pulpy mass in the center of each vertebral disk.

NUCLEUS TRACTUS SOLITARIUS (NTS). A group of nerve cells in the medulla that receives sensory information from the digestive tract (as well as the cardiovascular and respiratory systems) and conveys it to the vagus and facial nerves.

NULLIPARITY. The condition of being nulliparous, or not bearing offspring.

NUMBNESS. Loss of feeling or sensation.

NUTRIENT. A food substance that provides energy or is necessary for growth and repair. Examples of nutrients are vitamins, minerals, carbohydrates, fats, and proteins.

NYMPH. The immature louse that hatches from the nit.

NYSTAGMUS. An involuntary back-and-forth movement of the eyes that is often found in albinism.

O

OBESITY. Excessive weight due to accumulation of fat, usually defined as a body mass index (BMI) of 30 or above or body weight greater than 30% above normal on standard height-weight tables.

OBESITY PARADOX. The observation that, although obesity is usually linked to risk factors for various diseases and surgical complications, it sometimes appears to have a protective effect.

OBLIGATE CARNIVORE. An animal that must have meat in its diet to maintain health. Cats are obligate carnivores, although humans and most breeds of dogs are not.

OBSESSION. A repetitive or persistent thought, idea, or impulse that is perceived as inappropriate and distressing.

OBSESSIVE-COMPULSIVE DISORDER (OCD). An anxiety disorder characterized by obsessions, such as recurring thoughts or impulses, and compulsions, such as repetitive behaviors.

OBSTRUCTION. A blockage that prevents movement.

OBSTRUCTIVE SLEEP APNEA (OSA). A potentially life-threatening condition characterized by episodes of breathing cessation during sleep alternating with snoring or disordered breathing.

OCCIPITAL NEURALGIA. Pain on one side of the back of the head caused by entrapment or pinching of an occipital nerve.

OCCLUSION. An obstruction or blockage in a blood vessel.

OCCLUSION THERAPY. A type of treatment for amblyopia in which the good eye is patched for a period of time. This forces the weaker eye to be used.

OCCULT. Not visible or easily detected.

OCCULT BLOOD. Presence of blood that cannot be seen with the naked eye.

OCHRONOSIS. A rare hereditary condition that usually leads to arthritis in adulthood.

OCULAR FUNDUS. The part of the eye opposite the pupil.

OCULAR LARVA MIGRANS (OLM). A syndrome associated with toxocariasis, in which the eye is invaded by migrating larvae.

OCULAR MELANOMA. A malignant tumor that arises within the structures of the eye. It is the most common eye tumor in adults.

OCULAR NEOVASCULARIZATION. Abnormal or excessive formation of blood vessels in the eye.

OCULOPHARYNGEAL MUSCULAR DYSTROPHY (OPMD). Form of muscular dystrophy affecting adults of both sexes, and causing weakness in the eye muscles and throat.

ODYNOPHAGIA. Pain felt when swallowing.

OFF-LABEL USE. Drugs in the United States are approved by the Food and Drug Administration (FDA) for specific uses, periods of time, or dosages based on the results of clinical trials. However, it is legal for physicians to administer these drugs for other "off-label" or non-approved uses. It is not legal for pharmaceutical companies to advertise drugs for off-label uses.

OINTMENT. A thick substance that contains medicine and is meant to be spread on the skin, or if an ophthalmic ointment, in the eye.

OLIGURIA. Decreased urine production.

OMBUDSMAN. A patient representative who investigates patient complaints and problems related to hospital service or treatment. He or she may act as a mediator between the patient, the family, and the hospital.

OMEGA-3 FATTY ACIDS. A class of fatty acids which lowers the level of cholesterol in the blood. Omega-3 fatty acids are also essential for the growth and development of the brain and nerve tissue.

OMENTUM. The layer of peritoneal tissue that covers the abdominal organs. Its name comes from the Latin word for apron.

OMNIVORE. An animal whose teeth and digestive tract are adapted to consume either plant or animal matter. The term does not mean, however, that a given species consumes equal amounts of plant and animal products. Omnivores include bears, squirrels, opossums, rats, pigs, foxes, chickens, crows, monkeys, most dogs, and humans.

OMPHALOCELE. A congenital hernia in which a small portion of the fetal abdominal contents, covered by a membrane sac, protrudes into the base of the umbilical cord.

OMPHALOCELE. A congenital hernia in which a small portion of the fetal abdominal contents, covered by a membrane sac, protrudes into the base of the umbilical cord.

ONCHOCERCIASIS. Parasitic infestation caused by filamentous worms of the genus Onchocerca, especially *Onchocerca volvulus*, that is found in tropical America and is transmitted by several types of blackflies.

ONCOGENE. A gene that causes normal cell growth, but if mutated or expressed at high levels, encourages normal cells to change into cancerous cells.

ONCOLOGIST. A physician specializing in the diagnosis and treatment of cancer.

ONCOTIC PRESSURE. A form of osmotic pressure exerted by proteins (usually albumin) in blood plasma that tend to draw fluid into the circulatory system. It is also called colloid osmotic pressure.

ONYCHOLYSIS. The separation of a nail from its underlying bed. Onycholysis is a common symptom of candidal infections of the nail or of exposure to harsh chemicals and detergents.

ONYCHOMYCOSIS. The medical term for a fungal infection of the nails.

OOCYST. The egg form of the toxoplasmosis organism.

OOPHORECTOMY. Surgical removal of the ovary.

OPACITY. An opaque spot in a normally transparent structure, such as the lens of the eye.

OPEN BITE. A malocclusion in which some teeth do not meet the opposing teeth.

OPEN SURGERY. Surgery using a large incision to lay open an area for examination or treatment; in joint surgery, the whole joint is exposed.

OPHTHALMIA. Inflammation of the eye. Usually severe and affecting the conjunctiva. Trachoma is sometimes called Egyptian ophthalmia.

OPHTHALMIA NEONATORUM. The medical term for conjunctivitis in newborns.

OPHTHALMIC. Pertaining to the eye.

OPHTHALMIC ARTERY. The artery supplying the eye and adjacent structures with blood.

OPHTHALMOLOGIST. A physician specializing in the medical and surgical treatment of eye disorders.

OPHTHALMOLOGY. The branch of medicine that deals with the diagnosis and treatment of eye disorders.

WWW.BOOKBAZ.IR

OPHTHALMOSCOPE. A medical instrument which shines a light through the pupil of the patient's eye and illuminates the retina (back) of the eye, allowing a visual examination of the interior of the eye.

OPIATE. A drug containing or derived from opium—such as codeine, morphine, or heroin—that alleviates pain and induces sleep.

OPIATE BLOCKERS. A type of drug that blocks the effects of natural opiates in the system. This makes some people, including some people with autism, appear more responsive to their environment.

OPIOID. Any morphine-like synthetic narcotic that produces the same effects as drugs derived from the opium poppy (opiates), such as pain relief, sedation, constipation, and respiratory depression.

OPIOID ANTAGONIST. A type of receptor antagonist (drug) that acts on opioid receptors.

OPIOID RECEPTORS. Receptors located in the brain and various organs that bind opiates or opioid substances.

OPPORTUNISTIC. Causing disease only under certain conditions, as when a person is already sick or has a weak immune system.

OPPORTUNISTIC INFECTION. An infection by organisms that usually do not cause infection in people whose immune systems are working normally.

OPPOSITIONAL DEFIANT DISORDER. A childhood behavioral disorder characterized by an ongoing pattern of disobedient, hostile, and defiant behavior toward authority figures that goes beyond the bounds of normal childhood conduct.

OPTIC ATROPHY. Degeneration of the optic nerve.

OPTIC DISK. The small area in the retina where the optic nerve enters the eye that is not sensitive to light. Also called the blind spot.

OPTIC NERVE. The nerve that carries visual messages from the retina to the brain.

OPTIC NEURITIS. Inflammation of the optic nerve (cranial nerve II) which connects to the retina of the eye. This variable condition can be present with any of the following symptoms: blurred vision, loss of visual acuity, loss of some or all color vision, complete or partial blindness, and pain behind the eye.

OPTOKINETIC. A reflex that causes a person's eyes to move when his or her field of vision moves.

OPTOMETRIST. A medical professional who examines and tests the eyes for disease and treats visual disorders by prescribing corrective lenses and/or vision therapy. In many states, optometrists are licensed to use diagnostic and therapeutic drugs to treat certain ocular diseases.

ORAL AND MAXILLOFACIAL SURGEON. A dentist who is trained to perform surgery to correct injuries, defects, or conditions of the mouth, teeth, jaws, and face.

ORAL REHYDRATION SOLUTION (ORS). A liquid preparation developed by the World Health Organization that can decrease fluid loss in persons with diarrhea. Originally developed to be prepared with materials available in the home, commercial preparations have recently come into use.

ORAL SURGEON. A dentist who specializes in surgical procedures of the mouth, including extractions.

ORBIT. The cavity in the skull containing the eyeball; formed from seven bones: frontal, maxillary, sphenoid, lacrimal, zygomatic, ethmoid, and palatine.

ORBITAL COMPARTMENT SYNDROME. Compartment syndrome in the eye socket.

ORBITAL SEPTUM. A membrane-like sheet that functions as the anterior boundary of the orbit within the eye.

ORCHIECTOMY. Surgical removal of one or both testicles in a male; also called an orchidectomy.

ORCHIOPEXY. Surgical procedure that places the testicles in the scrotum.

ORCHITIS. Inflammation or swelling of the scrotal sac containing the testicles.

ORGAN PROCUREMENT. The process of donor screening and the evaluation, removal, preservation, and distribution of organs for transplantation.

ORGANELLE. Specialized structure within a cell, which is separated from the rest of the cell by a membrane composed of lipids and proteins, where chemical and metabolic functions take place.

ORGANIC BRAIN DISORDER. An organic brain disorder refers to impaired brain function due to damage or deterioration of brain tissue.

ORGANIC ILLNESS. A physically, biologically based illness.

ORGANIC MERCURY. Poisonous compounds containing mercury and carbon, such as methylmercury, ethylmercury, and phenylmercury.

ORGANISM. A single, independent life form, such as a bacterium, a plant, or an animal.

ORGASM. The climax of sexual excitement, usually characterized by vaginal contractions by the female and ejaculation of semen by the male.

ORGASMIC DISORDER. The impairment of the ability to reach sexual climax.

ORIGINATING SITE. The site where the patient receiving telehealth care is located.

OROPHARYNX. The part of the airway into which the mouth leads.

ORPHAN DISEASE. Another term for rare disease.

ORPHAN DRUG. A drug that treats a rare disease—"rare disease" being defined by the Food and Drug Association as one affecting fewer than 200,000 Americans. The category of orphan drug includes experimental as well as approved medications.

ORTHODONTIC TREATMENT. The process of realigning and straightening teeth to correct their appearance and function.

ORTHOGNATHIC SURGERY. Surgery to alter the relationships of the teeth and/or supporting bones, usually in conjunction with orthodontic treatment.

ORTHOKERATOLOGY. A method of reshaping the cornea using a contact lens. It is not considered a permanent method to reduce myopia.

ORTHOPAEDICS. The branch of surgery that treats deformities or disorders affecting the musculoskeletal system.

ORTHOPEDIC. Refers to surgery on the supporting structures of the body: bones, joints, ligaments, and muscles.

ORTHOPEDIC SURGERY. Surgery performed on the bones. May include joint replacements and surgery of the vertebrae.

ORTHOPEDICS. A medical specialty concerned with treating diseases, injuries, and malformations of the bones and supporting structures, such as tendons, ligaments, and muscles.

ORTHOPEDIST. A doctor who specializes in disorders of the musculoskeletal system.

ORTHOPNEA. Difficulty in breathing that occurs while the patient is lying down.

ORTHOPOXVIRUS. The genus of viruses that includes monkeypox, smallpox, cowpox, and camelpox.

ORTHOSTATIC HYPOTENSION. A drop in blood pressure that causes faintness or dizziness and occurs when one rises to a standing position. Also known as postural hypotension.

ORTHOTIC. An orthopedic device intended to compensate for the weakness of or damage to a limb as the result of disease or trauma.

ORTHOTIST. A healthcare professional who is skilled in making and fitting orthopedic appliances.

ORTHOTOPIC TRANSPLANTATION. The replacement of a whole diseased liver with a healthy donor liver.

OSLER'S NODES. Small, raised, reddish, tender areas associated with endocarditis, commonly found inside the fingers or toes.

OSMOLALITY. A measure of the solute-to-solvent concentration of a solution.

OSMOSIS. The movement of water (or another solvent) across a semipermeable membrane from an area of lower concentration of a solute toward an area of higher concentration.

OSMOTHERAPY. Intravenous injection or oral administration of an agent that induces dehydration. The goal of dehydration is to reduce the amount of accumulated fluid in the brain.

OSMOTIC DIURESIS. Increased urination caused by sugar or other substances in the urine.

OSMOTIC PRESSURE. Pressure that occurs when two solutions of differing concentrations are separated by a semipermeable membrane, such as a cellular wall, and the lower concentration solute is drawn across the membrane into the higher concentration solute (osmosis).

OSSICLES. The three small bones of the middle ear: the malleus (hammer), the incus (anvil) and the stapes (stirrup). These bones help carry sound from the eardrum to the inner ear.

OSTEITIS. Inflammation of the bone.

OSTEOARTHRITIS. The most common form of arthritis, characterized by erosion of the cartilage layer that lies between the bones in weight-bearing joints. It occurs mainly in older people.

OSTEOARTICULAR. Referring to a symptom or disorder that involves both bones and joints.

OSTEOBLAST. A type of bone cell that is responsible for bone formation. The number of osteoblasts in a person's body decreases with age.

WWW.BOOKBAZ.IR

OSTEOCLAST. A type of bone cell that removes bone tissue.

OSTEOCONDUCTION. Provision of a scaffold for the growth of new bone.

OSTEOCYTES. Bone cells that maintain bone tissue.

OSTEOGENESIS. Growth of new bone.

OSTEOGENESIS IMPERFECTA. A genetic disorder involving defective development of connective tissues, characterized by brittle and fragile bones that are easily fractured by the slightest trauma.

OSTEOINDUCTION. Acceleration of new bone formation by chemical means. Also refers to the process of building, healing, and remodeling bone in humans.

OSTEOLYSIS. Dissolution and loss of bone resulting from inflammation caused by particles of debris from a prosthesis.

OSTEOLYTIC LESION. Soft spot or hole in bone caused by cancer cells.

OSTEOMALACIA. A softening of bones caused by lack of vitamin D and/or calcium in the diet.

OSTEOMYELITIS. An infection of the bone that is usually treated with antibiotics but sometimes requires surgery.

OSTEOPATHY. A system of therapy that uses standard medical and surgical methods of diagnosis and treatment while emphasizing the importance of proper body alignment and manipulative treatment of musculoskeletal disorders. Osteopathy is considered mainstream primary care medicine rather than an alternative system.

OSTEOPENIA. Reduction in bone mass, usually caused by a lowered rate of formation of new bone that is insufficient to keep up with the rate of bone destruction.

OSTEOPHYTE. Also referred to as bone spur, it is an outgrowth or ridge that forms on a bone.

OSTEOPOROSIS. A condition found in older individuals in which bones decrease in density and become fragile and more likely to break. It can be caused by lack of vitamin D and/or calcium in the diet.

OSTEOTOMY. A surgical alternative to a hip prosthesis, in which the surgeon cuts through the pelvis or femur in order to realign the hip.

OSTIA. A mouth-like opening in a bodily part.

OSTOMY. An operation to create an opening from an area inside the body to the outside.

OTIC. Pertaining to the ear.

OTITIS MEDIA. Inflammation of the ear, which may be marked by pain, fever, abnormalities of hearing, hearing loss, tinnitus, and vertigo.

OTOLARYNGOLOGIST. A physician who diagnoses and treats disorders of the head and neck; sometimes called an ear, nose, and throat specialist or ENT.

OTOLOGIC. Relating to the study, diagnosis, and treatment of diseases of the ear and related structures.

OTOSCLEROSIS. A disease that scars and limits the motion of the small conducting bones in the middle ear.

OTOSCOPE. A hand-held instrument with a tiny light and a funnel-shaped attachment called an ear speculum, which is used to examine the ear canal and eardrum.

OTOTOXIC. Damaging to the nerves controlling the senses of hearing and balance.

OUTBREAK. A sudden increase in the incidence of a disease.

OUTPATIENT SURGERY. Also called same-day or ambulatory surgery. The patient arrives for surgery and returns home on the same day.

OVA. The reproductive cell of the female, which contains genetic information and participates in the act of fertilization. Also popularly called the egg.

OVAL WINDOW. A tiny opening at the entrance to the inner ear.

OVARIAN CYST. A benign or malignant growth on an ovary. An ovarian cyst can disappear without treatment or become extremely painful and have to be surgically removed.

OVARIAN FOLLICLES. Structures found within the ovary that produce eggs.

OVARIAN TORSION. Twisting of the ovary due to the influence of another condition or disease, resulting in extreme lower abdominal pain.

OVARY. One of two reproductive organs of women that are located in the pelvis; egg cells are developed and stored there, and the female sex hormones estrogen and progesterone are produced there.

OVERBITE. Protrusion of the upper teeth over the lower teeth.

OVERWEIGHT. A BMI between 25.0 and 30.0.

OVOLACTOVEGETARIAN. A vegetarian who consumes eggs and dairy products as well as plant-based

foods. The official diet recommended to Seventh-day Adventists is ovolactovegetarian.

OVOVEGETARIAN. A vegetarian who eats eggs in addition to plant-based foods.

OVULATION. The phase of the female monthly cycle when a developed egg is released from the ovary into the fallopian tube for possible fertilization.

OVUM. The reproductive cell of the female, which contains genetic information and participates in the act of fertilization. Also popularly called the egg.

OXALATE. A salt of oxalic acid produced during metabolism and excreted in the urine.

OXIDATION. Interaction in which one molecule removes an electron from another molecule to stabilize itself.

OXYCODONE. A narcotic painkiller that is widely abused.

OXYGEN FREE RADICALS. Reactive molecules containing oxygen and can cause cell damage.

OXYGENATED BLOOD. Blood carrying oxygen through the body.

OXYGENATION. Saturation with oxygen.

OXYTOCIN. A hormone secreted in the brains of mammals that acts as a neurotransmitter in the brain and also functions in sexual arousal, maternal behavior, and emotional bonding in humans. Synthetic oxytocin is used to induce or support labor in difficult childbirths.

OZONE. A gas found in the atmosphere. A layer of ozone about 15 mi (24 km) above Earth's surface helps protect living things from the damaging effects of the sun's ultraviolet rays.

P

P24 ANTIGEN. An HIV protein that is present in high concentrations early and again late in HIV infection and is often tested for in combination with HIV antibody testing.

PACEMAKER. An electrical device that has electrodes attached to the heart to electrically stimulate the heart to beat normally. Pacemakers can be internal (placed under the skin) or external, with the electrodes placed on the skin or threaded through a tube placed into the heart.

PAGET'S DISEASE OF BONE. Chronic disorder of unknown cause, usually affecting middle aged and elderly people, characterized by enlarged and deformed bones. Excessive breakdown and formation of bone tissue occurs with Paget's disease and can cause bone to weaken, resulting in bone pain, arthritis, deformities, and fractures.

PAGOPHAGIA. The compulsive eating of ice.

PAIN DISORDER. A psychiatric disorder in which pain in one or more parts of the body is caused or made worse by psychological factors. The lower back is one of the most common sites for pain related to this disorder.

PALATINE TONSILS. The tonsils that can be seen at the back of the throat and are the tonsils most commonly affected by tonsillitis.

PALEOLITHIC. Human cultures of the Pleistocene epoch, from about one million to 10,000 years ago.

PALLIATIVE. Referring to any type of treatment that is given to relieve the symptoms of a disease rather than to cure it.

PALLIDOTOMY. A surgical procedure that destroys a small part of a tiny structure within the brain called the globus pallidus internus. This structure is part of the basal ganglia, a part of the brain involved in the control of willed (voluntary) movement of the muscles.

PALLOR. Extreme paleness in the color of the skin.

PALPATE. To examine by means of touch.

PALPATION. A simple technique in which a doctor presses lightly on the surface of the body to feel the organs or tissues underneath.

PALPEBRAL FISSURE. Eyelid opening.

PALPITATION. Rapid, forceful, throbbing, or fluttering heartbeat.

PALSY. Uncontrollable tremors.

PANCARDITIS. Inflammation of the lining of the heart, the sac around the heart, and the muscle of the heart.

PANCHAKARMA. Intensive Ayurvedic cleansing and detoxification program.

PANCREAS. A large gland located on the back wall of the abdomen, extending from the duodenum (first part of the small intestine) to the spleen. The pancreas produces enzymes essential for digestion, and the hormones insulin and glucagon, which play a role in diabetes.

PANCREATECTOMY. Partial or total surgical removal of the pancreas.

WWW.BOOKBAZ.IR

PANCREATIC INSUFFICIENCY. Reduction or absence of pancreatic secretions into the digestive system due to scarring and blockage of the pancreatic duct.

PANCREATICODUODENECTOMY. Removal of all or part of the pancreas along with the duodenum. Also known as "Whipple's procedure" or "Whipple's operation."

PANCREATITIS. Inflammation of the pancreas.

PANDAS DISORDERS. A group of childhood disorders associated with such streptococcal infections as scarlet fever and "strep throat." The acronym stands for Pediatric Autoimmune Neuropsychiatric Disorders Associated with Streptococcal Infections. Sydenham's chorea is considered a PANDAS disorder.

PANDEMIC. The occurrence of a disease that in a short time infects a large percentage of the population over a wide geographical area.

PANHYPOPITUITARISM. Generalized decrease of all of the anterior pituitary hormones.

PANIC ATTACK. A time-limited period of intense fear accompanied by physical and cognitive symptoms. Panic attacks may be unexpected or triggered by specific internal or external cues.

PANIC DISORDER. A disorder in which people have sudden and intense attacks of anxiety in certain situations. Symptoms such as shortness of breath, sweating, dizziness, chest pain, and extreme fear often accompany the attacks.

PANNICULITIS. Inflammation of fatty tissue.

PAP (PAPANICOLAOU) SMEAR (PAP TEST). The common term for the Papanicolaou test, a simple smear method of removing cervical cells to screen for abnormalities that indicate cancer or a precancerous condition.

PAPAVERINE. A smooth muscle relaxant sometimes injected into the penis as a treatment for impotence.

PAPILLARY CARCINOMA. A type of breast cancer that primarily occurs in older women. On ultrasound, this type of tumor may look like a solid or complex mass, or it may show up as solid tissue protruding into a cyst.

PAPILLEDEMA. Swelling which occurs at the level of the optic nerve. Presence of papilledema is indicative of increased intracranial pressure.

PAPILLOMA. A benign growth on the skin or mucous membrane. Viruses that cause these growths are called human papillomaviruses (HPVs).

PAPILLOMAVIRUS. A member of a group of viruses associated with warts and cervical cancer.

PAPULE. An inflamed pimple near the surface of the skin.

PARACENTESIS. A procedure in which fluid is drained from a body cavity by means of a catheter placed through an incision in the skin.

PARALYSIS. The inability to voluntarily move.

PARAMYXOVIRUS. A genus of viruses that includes the causative agent of mumps.

PARANEOPLASTIC SYNDROME. A set of symptoms that is associated with cancer but is not directly caused by the cancer.

PARANOIA. An unfounded or exaggerated distrust of others.

PARAPHILIA. A type of sexual behavior in which a person derives sexual excitement from behavior that is unusual, extreme, or criminal.

PARAPHIMOSIS. The entrapment of a retracted foreskin behind the coronal sulcus, a groove that separates the shaft and head of the penis.

PARAPROTEIN. M-protein; abnormal immunoglobulin produced in multiple myeloma.

PARASITE. An organism that lives on or in another and takes nourishment (food and fluids) from that organism.

PARASITIC. Relating to a parasite.

PARASOMNIA. A primary sleep disorder in which the person's physiology or behaviors are affected by sleep, the sleep stage, or the transition from sleeping to waking.

PARASYMPATHETIC NERVOUS SYSTEM. A part of the autonomic nervous system that is concerned with conserving and restoring energy. It is the part of the nervous system that predominates in a state of relaxation.

PARASYMPATHOMIMETIC. An agent whose effects mimic those resulting from stimulation of the parasympathetic nerves.

PARATHYROID GLAND. Two pairs of smaller glands that lie close to the lower surface of the thyroid gland. They secrete parathyroid hormone, which regulates the body's use of calcium and phosphorus.

PARENTERAL NUTRITION. Nutrition supplied intravenously, thus bypassing the patient's digestive tract entirely.

PARESTHESIA. A prickly, tingling, or burning sensation on the skin.

PARIETAL CELLS. Specific cells which line the inside of the stomach. These cells are responsible for producing intrinsic factor and hydrochloric acid.

PARKINSON'S DISEASE. A neurological disorder caused by deficiency of dopamine, a neurotransmitter, which is a chemical that assists in transmitting messages between the nerves within the brain. It is characterized by muscle tremor or palsy and rigid movements.

PARKINSONISM. A group of conditions that all have these typical symptoms in common: tremor, rigidity, slow movement, and poor balance and coordination.

PARONYCHIA. Inflammation of the folds of skin that surround a nail.

PAROTID GLAND. The salivary gland that lies below and in front of each ear.

PAROTITIS. Inflammation and swelling of the salivary glands.

PAROXETINE HYDROCHLORIDE. An SSRI that is used to treat mental depression, OCD, anxiety, and various other disorders.

PAROXYSM. A sudden attack of symptoms.

PAROXYSMAL NOCTURNAL DYSPNEA (PND). A form of dyspnea characterized by the patient's waking from sleep unable to breathe.

PAROXYSMAL NOCTURNAL HEMOGLOBINURIA (PNH). A rare complement disorder characterized by episodes of red blood cell destruction (hemolysis) and blood in the urine (hemoglobinuria) that is worse at night.

PAROXYSMAL STAGE. The violent coughing stage of whooping cough.

PARTIAL DENTURE. A removable bridge that usually clasps onto only one abutment.

PARTIAL MASTECTOMY. Segmental mastectomy; removal of only the cancerous breast tissue and some of the surrounding normal tissue.

PARTIAL PARENTERAL NUTRITION (PPN). A solution, containing some essential nutrients, is injected into a vein to supplement other means of nutrition, usually a partially normal diet of food.

PARTIAL PRESSURE. The pressure exerted by one of the gases in a mixture of gases. The partial pressure of the gas is proportional to its concentration in the mixture. The total pressure of the gas mixture is the sum of the partial pressures of the gases in it (Dalton's law of partial pressure) and as the total pressure increases, each partial pressure increases proportionally.

PARTIAL SEIZURE. A seizure that starts in one particular part of the brain. The abnormal electrical activity may remain confined to that area, or may spread to the entire brain. Also called a focal seizure.

PARTIAL THROMBOPLASTIN TIME. A test used in conjunction with prothrombin time to determine the cause of clotting or bleeding problems.

PASSIVE IMMUNITY. Immunity produced by providing a person with antibodies from another source than self. Infants are born with passive immunity acquired from their mothers.

PASSIVE IMMUNIZATION. Treatment that provides immunity through the transfer of antibodies obtained from an immune individual.

PASTEURELLOSIS. A bacterial infection caused by *Pasteurella multocida*. Pasteurellosis is characterized by inflammation around the wound site and may be accompanied by bacteria in the bloodstream and infection in tissues and organs.

PASTEURIZATION. The process of partially sterilizing food using heat. Pasteurization destroys all harmful microorganisms without changing the food or killing the wanted microorganisms.

PASTIA'S LINES. Red lines in the folds of the skin, especially in the armpit and groin, that are characteristic of scarlet fever.

PATCH TEST. A skin test that is done to identify allergens. A suspected substance is applied to the skin. After 24 to 48 hours, if the area is red and swollen, the test is positive for that substance. If no reaction occurs, another substance is applied. This is continued until the patient experiences an allergic reaction at the site where the irritant was applied to the skin.

PATELLA. The kneecap; a triangular bone located at the front of the knee.

PATENCY. Being widely open. A blood vessel that has been widened or reopened is said to be patent.

PATENT DUCTUS ARTERIOSUS. A congenital defect in which the temporary blood vessel connecting the left pulmonary artery to the aorta in the fetus fails to close in the newborn.

PATERNAL. From one's father.

PATHOGEN. Any microorganism, virus, or other substance that causes disease in another organism.

WWW.BOOKBAZ.IR

PATHOGENIC. Disease-causing.

PATHOGENIC BACTERIA. Bacteria that produce illness.

PATHOLOGIC. Characterized by disease or the structural and functional changes due to disease. Pathologic heart murmurs may indicate a heart defect.

PATHOLOGICAL. Uncontrollable in nature; relating to disease.

PATHOLOGIST. A medical doctor that specializes in identifying diseases by studying cells and tissues under a microscope.

PATHOLOGY. The branch of medicine that looks at abnormal changes in cells and tissues which signal disease.

PATIENT YEARS. The number of patients multiplied by the number of years that they were followed in a study divided by the number of study events that occurred (in this case, the number of fainting episodes of the group).

PATIENT-CONTROLLED ANALGESIA (PCA). An approach to pain management that allows the patient to control the timing of intravenous doses of analgesic drugs.

PAVOR NOCTURNUS. Another term for sleep terror disorder.

PCI. A type of radiotherapy that is used to prevent tumors from growing in the brain.

PEAK FLOW. A measurement of the maximum speed of the patient's expiration (breathing out). It is also known as the peak expiratory flow rate or PEFR. Peak flow is measured by a small handheld device called a peak flow meter.

PECTUS CARINATUM. An abnormality of the chest in which the sternum (breastbone) is pushed outward. It is sometimes called "pigeon breast."

PECTUS EXCAVATUM. An abnormality of the chest in which the sternum (breastbone) sinks inward; sometimes called "funnel chest."

PEDIATRIC-AGED PATIENT. The pediatric-aged aged patient encompasses several periods during development. The first four weeks after birth are called the neonatal period, the first year after birth is called infancy, and childhood is from 13 months until puberty (between the ages of 12 and 15 years in girls and 13 and 16 years in boys).

PEDICLE FLAP. Also called an attached flap; this is a section of tissue, with its blood supply intact, which is maneuvered to another part of the body.

PEDICULICIDE. Any substance that kills lice.

PEDICULOSIS (PLURAL, PEDICULOSES). A lice infestation.

PEDOPHILIA. A sexual perversion in which children are the preferred sexual object.

PEG-ADA. An orphan drug that is useful in treating SCID related to ADA deficiency.

PELLEGRA. A condition caused by a dietary deficiency of one of the B vitamins called niacin.

PELVIC EXAM. A gynecological exam of the female reproductive organs.

PELVIC EXENTERATION. Extensive surgery to remove the uterus, ovaries, pelvic lymph nodes, part or all of the vagina, and the bladder, rectum, and/or part of the colon.

PELVIC INFLAMMATORY DISEASE (PID). Inflammation of the female reproductive tract, caused by any of several microorganisms. Symptoms include severe abdominal pain, high fever, and vaginal discharge. Severe cases can result in sterility. Also called PID.

PELVIC ORGANS. The organs inside of the body that are located within the confines of the pelvis. This includes the bladder and rectum in both sexes, and the uterus, ovaries, and fallopian tubes in females.

PEMPHIGUS. An autoimmune disorder in which the immune system produces antibodies against specific proteins in the skin and mucous membrane. These antibodies produce a reaction that leads to a separation of skin cells.

PENETRATING HEAD INJURY. TBI in which an object pierces the skull and enters brain tissue.

PENICILLAMINE (CUPRIMINE, DEPEN). A drug used to treat medical problems (such as excess copper in the body and rheumatoid arthritis) and to prevent kidney stones. It is also sometimes prescribed to remove excess lead from the body.

PENICILLIN. Relatively nontoxic antibiotics produced by molds in the genus *Pencillium*.

PENTAMIDINE ISOETHIONATE. An antibiotic used to treat and prevent PCP.

PEPSIN. A protease enzyme in the gastric juices of carnivorous and omnivorous animals that breaks down the proteins found in meat. Its existence in

humans is considered evidence that humans evolved as omnivores.

PEPTIC. A protease enzyme in the gastric juices of carnivorous and omnivorous animals that breaks down the proteins found in meat. Its existence in humans is considered evidence that humans evolved as omnivores.

PEPTIC ULCER. A wound in the lower stomach and duodenum caused by stomach acid and a newly discovered germ called *Helicobacter pylori*.

PEPTIC ULCER DISEASE (PUD). A stomach disorder marked by corrosion of the stomach lining due to the acid in the digestive juices.

PERCUSSION. An assessment method in which the surface of the body is struck with the fingertips to obtain sounds that can be heard or vibrations that can be felt. It can determine the position, size, and consistency of an internal organ. It is done over the chest to determine the presence of normal air content in the lungs, and over the abdomen to evaluate air in the loops of the intestine.

PERCUTANEOUS. Performed through the skin.

PERCUTANEOUS BIOPSY. A biopsy in which the needle is inserted and the sample removed through the skin.

PERCUTANEOUS TRANSHEPATIC CHOLANGIOGRAPHY. An x-ray examination of the bile ducts. A needle is passed through the skin (percutaneous) across or over the liver (transhepatic) and directly into a bile duct to inject a contrast dye. The dye enhances the x-ray image mapping the system of bile ducts (cholangiography).

PERCUTANEOUS TRANSLUMINAL CORONARY ANGIOPLASTY (PTCA). A cardiac intervention in which an artery blocked by plaque is dilated, using a balloon catheter to flatten the plaque and open the vessel; it is also called balloon angioplasty.

PERENNIAL. Present at all seasons of the year.

PERFECT USE. A measurement of the effectiveness of a contraceptive based only on those who use the method correctly and use it every time they have intercourse. It is also called the method effectiveness rate.

PERFORATION. A hole.

PERFUSION. The passage of fluid (such as blood) through a specific organ or area of the body (such as the heart).

PERFUSION LUNG SCAN. A scan that shows the pattern of blood flow in the lungs.

PERIAPICAL. Referring to the tissue surrounding the apex of a tooth's root.

PERICARDIAL EFFUSION. An accumulation of excess fluid in the pericardial sac which surrounds the heart.

PERICARDIAL TAMPONADE. The collection of blood in the sac surrounding the heart that causes compression.

PERICARDIOCENTESIS. A procedure used to drain fluid out of the sac surrounding the heart. This is done by inserting a needle through the chest and into the sac. Used to test for viruses, bacteria, and fungus. The physician puts a small tube through the skin, directly into the pericardial sac, and withdraws fluid. The fluid then is tested for viruses, bacteria, and fungus.

PERICARDITIS. Inflammation of the pericardium, the membrane surrounding the heart.

PERICARDIUM. The pericardium is the thin, sac-like membrane that surrounds the heart. It has two layers: the serous pericardium and the fibrous pericardium.

PERICORONITIS. A gum condition in which irritation and inflammation are produced by the crown of an incompletely erupted tooth.

PERINATAL. Refers to the period shortly before and after birth, generally from around the twentieth week of pregnancy to one to four weeks after birth.

PERINATOLOGIST. A specialist in the branch of obstetrics that deals with the high-risk pregnant woman and her fetus.

PERINEAL. The diamond-shaped region of the body between the pubic arch and the anus.

PERINEUM. The area between the thighs that lies behind the genital organs and in front of the anus.

PERIODIC LIMB MOVEMENTS IN SLEEP (PLMS). Random movements of the arms or legs that occur at regular intervals of time during sleep.

PERIODONTAL. Pertaining to the gums.

PERIODONTITIS. A gum disease that destroys the structures supporting the teeth, including bone.

PERIOSTEUM. A fibrous vascular membrane that covers bones.

PERIPHERAL ARTERIAL DISEASE (PAD). Damage to the arteries outside of the heart; especially narrowing or obstruction of an artery supplying a leg.

WWW.BOOKBAZ.IR

PERIPHERAL NERVES. Nerves that carry information to and from the spinal cord.

PERIPHERAL NERVOUS SYSTEM (PNS). The part of the nervous system that is outside the brain and spinal cord. Sensory, motor, and autonomic nerves are included.

PERIPHERAL NEUROPATHY. A disease affecting the portion of the nervous system outside the brain and spinal chord. One or more nerves can be involved, causing sensory loss, muscle weakness and shrinkage, and decreased reflexes.

PERIPHERAL PRECOCIOUS PUBERTY. Precocious puberty resulting from the presence of sex steroids independent of the activation of the HPG axis. It is also called precocious pseudopuberty.

PERIPHERAL STEM CELLS. Stem cells that are taken directly from the circulating blood and used for transplantation. Stem cells are more concentrated in the bone marrow, but they can also be extracted from the bloodstream.

PERIPHERAL VASCULAR DISEASE. A disease affecting blood vessels, especially in the arms, legs, hands, and feet.

PERIPHERAL VISION. The ability to see objects that are not located directly in front of the eye. Peripheral vision allows people to see objects located on the side or edge of their field of vision.

PERISTALSIS. The waves of muscular contraction in the intestines that push the food along during the process of digestion.

PERITONEAL FLUID. Fluid from the abdominal cavity.

PERITONEUM. The transparent membrane lining the abdominal cavity that holds internal organs in place.

PERITONITIS. Inflammation of the layer of tissue that lines the inside of the abdominal cavity.

PERMEABLE. Capable of allowing substances to pass through.

PERMETHRIN. A common neurotoxic insecticide and insect repellent that it used to treat clothing and equipment.

PERNICIOUS ANEMIA. Type of anemia caused by a deficiency in vitamin B_{12}.

PEROXIDE. A bleaching agent that is a compound consisting of two atoms of oxygen connected by a single bond.

PEROXINS. Proteins that are responsible for forming the peroxisomal membrane and transporting other proteins into the peroxisome; these proteins are encoded by various PEX genes.

PEROXISOME. A cellular organelle or microbody that contains various enzymes that are responsible for the production of cellular components and the breakdown of toxic waste products.

PEROXISOME BIOGENESIS DISORDER (PBD). An inherited disorder, such as Zellweger syndrome and other Zellweger spectrum disorders, that disrupt the formation and functioning of peroxisomes.

PERPETRATOR. The legal term for a person who commits a crime.

PERSECUTORY DELUSION. A fixed, false, and inflexible belief that others are engaging in a plot or plan to harm an individual.

PERSEVERATION. Continuous involuntary repetition of speech or behavior.

PERSONAL CARE ATTENDANT. An employee hired either through a healthcare facility, home care agency, or private agency to assist a patient in performing ADLs.

PERSONALITY. The organized pattern of behaviors and attitudes that makes a human being distinctive. Personality is formed by the ongoing interaction of temperament, character, and environment.

PERSONALIZATION. The tendency to refer large-scale events or general patterns of events to the self in inappropriate ways. For example, a person who regards the loss of a loved one in an accident as punishment for having quarreled with that person before the accident is said to be personalizing the event. This tendency increases a person's risk of developing ASD or PTSD after a traumatic event.

PERSONALIZED MEDICINE. The use of genetic information and other new discoveries to customize medical diagnosis and treatment for the individual patient. Integrative medicine is considered one approach to personalized medicine.

PERTUSSIS. Whooping cough.

PERVASIVE DEVELOPMENTAL DISORDER (PDD). Used by the American Psychiatric Association for individuals who meet some but not all of the criteria for autism.

PESCE/POLLO VEGETARIAN. A term used to describe semivegetarians; that is, people who avoid the use of red meat but will include fish (*pesce* in Italian) or

chicken (*pollo* in Italian) in the diet. Other terms for semivegetarians include *piscitarian* or *fishetarian* for those who eat only fish but not chicken, and *pollovegetarian* or *pollotarian* for those who add chicken but not fish to their vegetarian diet.

PESSARY. A device inserted into the vagina to support sagging organs.

PETECHIA. A small, round, reddish purple spot on the skin, representing a tiny area of bleeding under the skin.

PETROLEUM JELLY OR OINTMENT. Petrolatum, a gelatinous substance obtained from oil that is used as a protective dressing.

PEYRONIE'S DISEASE. A disease resulting from scarring of the corpus cavernosa, causing painful erections.

PH. A measurement of acid or alkali (base) of a solution based on the amount of hydrogen ions available. Based on a scale of 14, a pH of 7.0 is neutral. A pH below 7.0 is an acid; the lower the number, the stronger the acid. A pH above 7.0 is a base; the higher the number, the stronger the base. Blood pH is slightly alkali with a normal range of 7.36–7.44.

PHACOEMULSIFICATION. Surgical procedure to remove a cataract using sound waves to disintegrate the lens which is then removed by suction.

PHAGOCYTIC CELLS. A specialized white blood cell that protects the body by ingesting bacteria, foreign particles, and dead or dying cells.

PHAGOCYTOSIS. A process by which a white blood cell envelopes and digests debris and microorganisms to remove them from the blood.

PHALANX. Any of the digital bones of the hand or foot. Humans have three phalanges to each finger and toe with the exception of the thumb and big toe which have only two each.

PHALILALIA. Involuntary echoing of the last word, phrase, sentence, or sound vocalized by oneself.

PHANTOM LIMB/PAIN. The perception that a limb is present (and throbbing with pain) after it has been amputated.

PHARMACEUTICAL. Pertaining to drugs.

PHARMACO-DYNAMICS. The study of the relationships and interactions of herbs.

PHARMACOLOGIC CARDIOVERSION. The use of medications to restore normal heart rhythm. It is also called chemical cardioversion.

PHARMACOLOGICAL. Referring to therapy that relies on drugs.

PHARYNGITIS. Inflammation of the throat, accompanied by dryness and pain. Pharyngitis caused by a streptococcal infection is the usual trigger of Sydenham's chorea.

PHARYNX. The pharynx is the part of the throat that lies between the mouth and the larynx or voice box.

PHASE CONTRAST MICROSCOPE. A light microscope in which light is focused on the sample at an angle to produce a clearer image.

PHENOTHIAZINE-DERIVATIVE DRUGS. A large family of drugs derived from phenothiazine, a compound that in itself is too poisonous for human consumption. Phenothiazine derivatives include tranquilizers, medications that prevent vomiting, antihistamines, and drugs used to enhance the effectiveness of anesthesia.

PHENOTYPE. A trait produced by a gene. For example, the specific HLA antigen(s) inherited for the HLA-A locus is the phenotype for that gene.

PHENYLALANINE. An essential amino acid that must be obtained from food since the human body cannot manufacture it.

PHENYLKETONURIA (PKU). A genetic disorder in which the body lacks an important enzyme. If untreated, the disorder can lead to brain damage and intellectual disabilities (ID).

PHEOCHROMOCYTOMA. A tumor that originates from the adrenal gland's chromaffin cells, causing overproduction of catecholamines, powerful hormones that induce high blood pressure and other symptoms.

PHEOCHROMOCYTOMA. A tumor that originates from the adrenal gland's chromaffin cells, causing overproduction of catecholamines, powerful hormones that induce high blood pressure and other symptoms.

PHILADELPHIA CHROMOSOME. An abnormal chromosome that is found in patients with a chronic form of leukemia but not in PV patients.

PHIMOSIS. A tightening of the foreskin that may close the opening of the penis.

PHLEBITIS. Inflammation of a vein.

WWW.BOOKBAZ.IR

PHLEBOTOMIST. A person specially trained to withdraw blood from a vein for testing, research, or transfusion.

PHLEBOTOMY. The taking of blood from the body through an incision in the vein, usually in the treatment of disease.

PHLEBOVIRUS. A genus of RNA viruses that belongs to the family Bunyaviridae. Heartland virus is a phlebovirus.

PHLEGM. Thick mucus produced in the air passages.

PHOBIA. An intense and irrational fear of a specific object, activity, or situation.

PHONICS. A system to teach reading by teaching the speech sounds associated with single letters, letter combinations, and syllables.

PHOROPTER. The instrument used to measure refractive status of the eyes. It contains many lenses which are then changed in front of the eyes while the patient is looking at an eye chart. This is when the doctor usually asks, "Which is better, one or two?"

PHOSPHODIESTERASE–5 (PDE5) INHIBITORS. The drugs Viagra, Levitra, and Cialis, which are used to treat ED.

PHOTOCHEMOTHERAPY (PUVA). A combination of ultraviolet A light and medication for treating psoriasis.

PHOTOCOAGULATION. Cancer treatment in which the tumor is destroyed by an intense beam of laser light.

PHOTOCONJUNCTIVITIS. Swelling of the conjunctiva of the eye as a result of exposure to ultraviolet light.

PHOTODYNAMIC THERAPY (PDT). A treatment for tumors in which a light-sensitive dye is injected into the blood (or skin) to be taken up selectively by the tumors. Light of a specific wavelength is then applied to the affected area to kill the tumors.

PHOTOKERATITIS. Swelling of the cornea of the eye as a result of exposure to ultraviolet light.

PHOTON. A light particle.

PHOTOPHOBIA. An extreme sensitivity to light.

PHOTOPIGMENT. Pigment that is most sensitive to a particular wavelength of light.

PHOTORECEPTORS. Specialized nerve cells (rods and cones) in the retina that are responsible for vision.

PHOTOREFRACTIVE KERATECTOMY (PRK). A type of refractive eye surgery using a laser to change the shape of the cornea.

PHOTOSENSITIVITY. An abnormally heightened reaction to light.

PHOTOSENSITIZER. A chemical compound that can be excited (activated) by light of a specific wavelength.

PHOTOTHERAPY. Also called light therapy, the patient is exposed to a bright light to compensate for reduced exposure to sunlight.

PHOTOTOXIC. Causes a harmful skin reaction when exposed to sunlight.

PHYSIATRIST. A physician who specializes in physical medicine and rehabilitation.

PHYSICAL ACTIVITY. Any activity that involves moving the body and burning calories.

PHYSICAL FITNESS. A combination of muscle strength, cardiovascular health, and flexibility that is usually attributed to regular exercise and good nutrition.

PHYSICAL MANIPULATION. The use of deep massage, spinal alignment, and joint manipulation to stimulate tissues.

PHYSIOLOGIC. Refers to physiology, particularly normal, healthy, physical functioning.

PHYSIOLOGICAL. Pertaining to the functioning of an organ, as governed by the interactions between its physical and chemical conditions.

PHYTATE. Plant compound that binds minerals, reducing their ability to be absorbed.

PHYTO-, AS IN PHYTOCHEMICAL, PHYTOMEDICINAL, AND PHYTOTHERAPY. Meaning, or pertaining to, a plant or plants.

PHYTOESTROGEN. An estrogen-like substance produced by plants.

PIA MATER. The innermost layer of the meninges.

PICA. An abnormal appetite or craving for nonfood items, often such substances as chalk, clay, dirt, laundry starch, or charcoal.

PICK'S DISEASE. A rare type of primary major neurocognitive disorder that affects the frontal lobes of the brain. It is characterized by a progressive loss of social skills, language, and memory, leading to personality changes and sometimes loss of moral judgment.

PILOCARPINE. A drug used to treat dry mouth and glaucoma, also used to induce sweating in the sweat test that is used to help diagnose cystic fibrosis.

PINWORM. Enterobiusital vermicularisital, a nematode worm of the family Oxyuridae that causes parasitic infestation of the intestines and cecum. Pinworm is endemic in both temperate and tropical regions and common especially in school age children.

PIPERONYL BUTOXIDE. A liquid organic compound that enhances the activity of insecticides.

PIRIFORMIS. A muscle in the pelvic girdle that is closely associated with the sciatic nerve.

PITTING EDEMA. When a swollen area is pressed, the pressure leaves an indentation (pit) that takes time to fill back in.

PITUITARY GLAND. Often referred to as the master gland within the endocrine system. Produces hormones that control the functions of other glands within the endocrine system. Controls many body functions especially growth.

PLACEBO. A pill or liquid given during the study of a drug or dietary supplement that contains no medication or active ingredient. Usually study participants do not know if they are receiving a pill containing the drug or an identical-appearing placebo.

PLACENTA. The organ that provides oxygen and nutrition from the mother to the unborn baby during pregnancy. The placenta is attached to the wall of the uterus and leads to the unborn baby via the umbilical cord.

PLACENTA PREVIA. A low-lying placenta that covers part or all of the inner opening of the cervix. This can result in heavy bleeding during labor and delivery, which can be dangerous for mother and baby.

PLACENTAL ABRUPTION. Separation of the placenta from the uterine wall, cutting off blood flow to the fetus.

PLAGUE. A highly infectious disease that can be fatal if not treated promptly. The bacteria that cause plague mainly infect rats, mice, squirrels, and other wild rodents. The disease is passed to people through fleas. Infected people can then spread the disease to other people.

PLANTAR FASCIA. A tough fibrous band of tissue surrounding the muscles of the sole of the foot. Also called plantar aponeurosis.

PLAQUE. A deposit of fatty and other substances that accumulates in the lining of the artery wall.

PLASMA. Clear, yellow- or straw-colored fluid that is the liquid component of blood and lymphatic fluid.

PLASMA CELL. Type of white blood cell that produces antibodies; derived from an antigen-specific B-cell.

PLASMALOGEN. Any of a group of phospholipids; plasmalogen synthesis is disrupted in ZS.

PLASMAPHERESIS. Plasma exchange, or the removal of the liquid portion of the blood, separating it from blood cells and returning the cells with healthy plasma.

PLASTINATION. A technique for preserving an anatomical specimen by replacing water and fat with plastics, yielding a specimen that can be preserved indefinitely for later study and does not smell or decay.

PLATELET. A small, disk-shaped body in the blood that has an important role in blood clotting. They form the initial plug at the rupture site of a blood vessel.

PLATELET AGGREGATION. The clumping together of blood cells, possibly forming a clot.

PLATYPNEA. Dyspnea that occurs when the patient is sitting up.

PLETHYSMOGRAPHY. A test in which a patient sits inside a booth called a plethysmograph and breathes through a mouthpiece, while pressure and air flow measurements are collected to measure the total lung volume.

PLEURA. A delicate membrane that encloses the lungs. The pleura is divided into two areas separated by fluid—the visceral pleura, which covers the lungs, and the parietal pleura, which lines the chest wall and covers the diaphragm.

PLEURAL CAVITY. The area of the chest that includes the lining of the chest cavity, the space the lungs are located in, and the membrane covering of the lungs.

PLEURAL EFFUSION. An abnormal accumulation of fluid in the pleura, a fibrous membrane that lines the inside of the chest cavity and protects the lungs. This accumulation can cause shortness of breath, cough, and chest pain.

PLEURAL SPACE. The small space between the two layers of the membrane that covers the lungs and lines the inner surface of the chest.

PLEURISY. Chest pain that occurs when a person takes a deep breath.

WWW.BOOKBAZ.IR

PLEURITIS. Inflammation of the pleura, the membrane surrounding the lungs.

PNEUMOCOCCAL CONJUGATE VACCINE (PCV13). A vaccine that helps protect against the 13 serotypes of *Streptococcus pneumoniae* that cause the most severe illness in children.

PNEUMOCOCCAL PNEUMONIA. Pneumonia caused by the bacterium *Streptococcus pneumoniae*.

PNEUMOCOCCAL POLYSACCHARIDE VACCINE (PPSV23). Pneumovax; a vaccine that protects against pneumonia caused by 23 serotypes of *Streptococcus pneumoniae*.

PNEUMOCOCCUS. *Streptococcus pneumoniae* that causes acute pneumonia affecting one or both lungs.

PNEUMOCONIOSIS (PLURAL, PNEUMOCONIOSES). Any chronic lung disease caused by inhaling particles of silica or similar substances that lead to loss of lung function.

PNEUMOCYSTOSIS. Another name for active PCP infection.

PNEUMONIA. A disease in which the lungs become inflamed. Pneumonia may be caused by bacteria, viruses, or other organisms, or by physical or chemical irritants.

PNEUMONITIS. Inflammation of the lungs.

PNEUMONITIS (ASPIRATION). Inflammation of the lung caused by inhaling a liquid, usually carbon based.

PNEUMOPERITONEUM. The presence of air or gas in a cavity.

PNEUMOTHORAX. A collection of air or gas in the chest cavity that causes a lung to collapse. Pneumothorax may be caused by an open chest wound that admits air.

PODIATRIST. A physician who specializes in the medical care and treatment of the human foot.

PODIATRY. A medical specialty concerned with treating diseases, injuries, and malformations of the feet.

PODOPHYLLUM RESIN. A medication derived from the May apple or mandrake and used to treat genital warts.

POINT OF VIEW. In a person with dyslexia, this term is used to describe the angle from which their mind's eye views an object. This point of view may be unanchored and moving about, as if several different people were telling what they see all at the same time.

POLYARTHRITIS. A nonspecific term for arthritis involving two or more joints, typically associated with autoimmune forms of arthritis. Symptoms usually include pain, inflammation, and/or swelling in multiple joints.

POLYCARBONATE. A very strong type of plastic often used in safety glasses, sport glasses, and children's eyeglasses. Polycarbonate lenses have approximately 50 times the impact resistance of glass lenses.

POLYCYSTIC KIDNEY DISEASE. A hereditary kidney disease that causes fluid- or blood-filled pouches of tissue called cysts to form on the tubules of the kidneys. These cysts impair normal kidney function.

POLYCYSTIC OVARIAN SYNDROME (PCOS). A condition in which the eggs are not released from the ovaries and instead form multiple cysts.

POLYCYTHEMIA VERA. A condition characterized by an unusually large number of red blood cells in the blood due to increased production by the bone marrow. Symptoms include headaches, blurred vision, high blood pressure, dizziness, and night sweats.

POLYDIPSIA. Excessive thirst.

POLYDRUG-RESISTANT (PDR). Bacteria that are resistant to multiple antibiotics.

POLYGENIC. A trait or disorder that is determined by several different genes. Most human characteristics, including height, weight, and general body build, are polygenic. Schizophrenia and late-onset AD are considered polygenic disorders.

POLYMER. A substance formed by joining smaller molecules. For example, plastic, acrylic, cellulose acetate, cellulose propionate, nylon, etc.

POLYMERASE CHAIN REACTION (PCR). A powerful technique for detecting DNA or RNA from minute quantities of an infectious agent, such as a virus.

POLYMORPHISM. A change in the base pair sequence of DNA that may or may not be associated with a disease.

POLYMYOSITIS. An inflammation of many muscles.

POLYP. An abnormal growth of tissue arising from and protruding from a mucous membrane.

POLYPOSIS. The medical term for the development of multiple polyps on a body part.

POLYSACCHARIDE. A complex carbohydrate that consists of long chains of monosaccharides bound together.

POLYSOMNOGRAPHY. Laboratory measurement of a patient's basic physiological processes during sleep. Polysomnography usually measures eye movement, brain waves, and muscular tension.

POLYTRAUMA. The medical term for injury to more than one part of the body or more than one type of injury (such as burn injuries in addition to broken bones).

POLYUNSATURATED FAT. A fatty acid molecule with two or more double bonds, known to be beneficial to health when consumed in moderate amounts. A type of fat found in some vegetable oils, such as sunflower, safflower, and corn.

POLYURIA. Excessive production of urine.

PONTIC. An artificial tooth.

PORCELAIN GALLBLADDER. A condition in which calcium is deposited in the walls of the gallbladder, causing the organ to become whitish or bluish-white in appearance and brittle.

PORNOGRAPHY. Sexually explicit pictures, writings, or other material produced for the purpose of sexual arousal.

PORPHYRIAS. A group of disorders involving heme biosynthesis, characterized by excessive excretion of porphyrins. The porphyrias may be either inherited or acquired (usually from the effects of certain chemical agents).

PORPHYRIN. A type of pigment found in living things.

PORTABLE CHEST X-RAY. An x-ray procedure taken by equipment that can be brought to the patient. The resulting radiographs may not be as high in quality as stationary x-ray radiographs, but they allow a technologist to come to the patient.

PORTAL. An entrance or a means of entrance.

PORTAL HYPERTENSION. Extreme pressure on the blood vessels of the liver.

PORTAL VEIN. The blood vessel carrying venous blood from the abdominal organs to the liver.

PORTAL VEIN THROMBOSIS. The development of a blood clot in the vein that brings blood into the liver. Untreated portal vein thrombosis causes portal hypertension.

POSITIVE SYMPTOMS. Symptoms of schizophrenia that are characterized by the production or presence of behaviors that are grossly abnormal or excessive, including hallucinations and thought-process disorder.

POSITRON. One of the small particles that make up an atom. A positron has the same mass and amount of charge as an electron, but the positron has a positive charge.

POSITRON EMISSION TOMOGRAPHY (PET) SCAN. An imaging system that creates a picture showing the location of tumor cells in the body. A substance called radionuclide dye is injected into a vein, and the PET scanner rotates around the body to create the picture. Malignant tumor cells show up brighter in the picture because they are more active and take up more dye than normal cells.

POST-CONCUSSION SYNDROME. A complex of symptoms including headache following mild TBI.

POST-DEPLOYMENT SYNDROME (PDS). A term developed recently to describe a constellation of mental disorders found in veterans of the conflicts in Iraq and Afghanistan. PDS includes PTSD, generalized anxiety disorder, major depression, chronic pain, and traumatic brain injury.

POSTDROME. The post-headache phase of a migraine in which cerebral blood flow remains abnormal.

POST-EXPOSURE PROPHYLAXIS (PEP). A course of antiretroviral drugs administered immediately following exposure to HIV, in the hope of preventing infection.

POST-HERPETIC NEURALGIA. Lingering pain that can last for years after an attack of shingles.

POSTMENOPAUSAL. A term referring to the time period following menopause.

POSTMORTEM. After death.

POSTPARTUM. Refers to the six-week period after childbirth.

POST-TRAUMATIC AMNESIA (PTA). Difficulty forming new memories after TBI.

POST-TRAUMATIC STRESS DISORDER (PTSD). A disorder that occurs among survivors of severe environmental stress such as a tornado, an airplane crash, or military combat. Symptoms include anxiety, insomnia, flashbacks, and nightmares. Patients with PTSD are unnecessarily vigilant; they may experience survivor guilt, and they sometimes cannot concentrate or experience joy.

POSTURAL DRAINAGE. The use of positioning to drain secretions from the bronchial tubes and lungs into the trachea or windpipe.

WWW.BOOKBAZ.IR

POTABLE. Safe to drink.

POTASSIUM. A mineral found in whole grains, meat, legumes, and some fruits and vegetables. Potassium is important for many body processes, including proper functioning of the nerves and muscles.

POTENTIZATION. The process of increasing the power of homeopathic preparations by successive dilutions and successions of a mother tincture.

POTENTIZE. The process of transferring the healing energy of a plant into spring water.

POVERTY OF SPEECH. A negative symptom of schizophrenia, characterized by brief and empty replies to questions. It should not be confused with shyness or reluctance to talk.

POX. A pus-filled bump on the skin.

PRAKRITI. An individual's unique dosha pattern.

PRANA. Basic life energy found in the elements.

PRANAYAMA. Yoga breathing techniques.

PRECANCEROUS. Abnormal and with a high probability of turning into cancer, but not yet a cancer.

PRECOCIOUS. Developing at an unusually early age.

PRECONCEPTIONAL. This refers to the time period before pregnancy, i.e., conception, occurs.

PREDNISONE. A corticosteroid often used to treat inflammation.

PREECLAMPSIA. A serious disorder of late pregnancy in which the blood pressure rises, there is a large amount of retained fluids, and the kidneys become less effective and excrete proteins directly into the urine.

PREECLAMPSIA AND ECLAMPSIA. Disorders of late pregnancy associated with high blood pressure, fluid retention, and protein in the urine. They can cause stillbirth.

PREFORMED VITAMIN A. Retinol and retinyl ester that are obtained from animal sources—fish, meat (especially liver) and dairy products—and that are used directly by the body or metabolized to retinal and retinoic acid.

PREGNANCY CATEGORY. A system of classifying drugs according to their established risks for use during pregnancy. Category A: Controlled human studies have demonstrated no fetal risk. Category B: Animal studies indicate no fetal risk, but no human studies; or adverse effects in animals, but not in well-controlled human studies. Category C: No adequate human or animal studies; or adverse fetal effects in animal studies, but no available human data. Category D: Evidence of fetal risk, but benefits outweigh risks. Category X: Evidence of fetal risk. Risks outweigh any benefits.

PREMALIGNANT SKIN LESION. An abnormal change in the skin that has a good chance of turning into skin cancer but is not yet cancerous.

PREMATURE ATRIAL BEAT. A beat that occurs before it would normally be expected.

PREMATURE DELIVERY. The birth of a live baby when a pregnancy ends spontaneously after the twentieth week.

PREMATURE EJACULATION. Rapid ejaculation before the person wishes it, usually in less than one to two minutes after beginning intercourse.

PREMENSTRUAL SYNDROME (PMS). An array of symptoms—including anxiety, irritability, depression, fatigue, insomnia, headache, and bloating—that affects some women prior to the onset of menstruation.

PREMIUM. The amount paid by a beneficiary for insurance coverage, usually on a monthly basis.

PREMUTATION. A change in a gene that precedes a mutation; this change does not alter the function of the gene.

PRENATAL DIAGNOSIS. The determination of whether a fetus possesses a disease or disorder while it is still in the womb.

PRENATAL INFECTION. A maternal infection that is vertically transmitted to the fetus through the placenta.

PRENATAL TESTING. Testing for a disease, such as a genetic condition, in an unborn baby.

PREPUCE. The fold of tissue covering the clitoris in females and the tip of the penis in males.

PREPUCE. The fold of tissue covering the clitoris in females and the tip of the penis in males.

PRESBYOPIA. A condition affecting people over the age of 40 where the system of accommodation that allows focusing of near objects fails to work because of age-related hardening of the lens of the eye.

PRESENILE DEMENTIA. The original name for Alzheimer's disease.

PRESENILIN (PSEN). Presenilin 1 and presenilin 2 are proteins that are involved in processing amyloid

precursor protein (APP). Mutations in the genes encoding these proteins can cause early-onset AD.

PRESENTATION. The part of the fetus's body that enters into the birth canal first.

PRESSURE POINTS. Specific locations on the feet and hands that correspond to nerve endings that connect to the organs and glands of the human body via the spinal cord.

PRETERM LABOR. Labor before the thirty-seventh week of pregnancy.

PREVALENCE. The percentage of a population that is affected by a specific disease at a given time.

PRIAPISM. A prolonged erection lasting more than four hours.

PRIMARY CARE. Medical care offered by a physician, physician assistant, nurse practitioner, or other healthcare provider who is the patient's first contact with the healthcare system before the patient is referred to a specialist elsewhere in the system.

PRIMARY ENERGY PATTERN. A spiral motion that radiates from the umbilicus; the energy pattern associated with a child in the womb.

PRIMARY GAIN. The immediate relief from guilt, anxiety, or other unpleasant feelings that a patient derives from a symptom.

PRIMARY HEADACHE. A headache that is not caused by another disease or medical condition. Tension headaches are a subtype of primary headache.

PRIMARY PERSONALITY. The core personality of an DID patient. In women, the primary personality is often timid and passive, and may be diagnosed as depressed.

PRIMARY PROGRESSIVE. A pattern of symptoms of multiple sclerosis in which the disorder progresses without remission, or with occasional plateaus or slight improvements.

PRIMARY SCLEROSING CHOLANGITIS. A chronic disease in which it is believed that the immune system fails to recognize the cells that compose the bile ducts as part of the same body, and attempts to destroy them. It is not clear what exactly causes the disease, but it is frequently associated with another inflammatory disease of the digestive tract, ulcerative colitis. The inflammation of the ducts eventually produces formation of scar tissue, causing multiple areas of narrowing (strictures) that block bile flow and lead to bacterial infection. Liver transplant gives the best chance for long-term survival.

PRIMARY SLEEP DISORDER. A sleep disorder that cannot be attributed to a medical condition, another mental disorder, or prescription medications or other substances.

PRIMARY TEETH. A child's first set of teeth, sometimes called baby teeth.

PROBENECID. A drug that corrects hyperuricemia by increasing the urinary excretion of urate.

PROBIOTICS. Food supplements containing live bacteria or other microbes intended to improve or restore the normal balance of microorganisms in the digestive tract.

PROCAINE PENICILLIN. An injectable form of penicillin that contains an anesthetic to reduce the pain of the injection.

PROCESS ADDICTION. Addiction to certain mood-altering behaviors, such as eating, gambling, sexual activity, overwork, and shopping.

PROCESSUS VAGINALIS. A pouch of the peritoneum (lining of the abdominal cavity) that is carried into the scrotum with the descent of the testicles to become the tunica vaginalis.

PROCTITIS. Inflammation of the anus and rectum.

PROCTOSCOPE. An instrument consisting of a thin tube with a light source, used to examine the inside of the rectum.

PROCTOSCOPY. A procedure in which a thin tube containing a camera and a light is inserted into the rectum so that the doctor can visually inspect it.

PROCTOSIGMOIDOSCOPY. A visual examination of the rectum and sigmoid colon using a sigmoidoscope, also known as sigmoidoscopy.

PRODROME. A period before the acute phase of a disease when the patient notices characteristic warning symptoms.

PROGESTERONE. A hormone naturally secreted by the ovary, or manufactured synthetically, that prepares the uterus for implantation of a fertilized egg.

PROGESTERONE RECEPTOR (PR). A cell-surface protein that binds the female hormone progesterone; breast cancer cells are often PR-positive.

PROGESTIN. Any natural or synthetic hormone that causes the effects of progesterone.

PROGNOSIS. The predicted outcome of a disease.

PROGRESSIVE. A term that refers to a disease that gets worse over time.

WWW.BOOKBAZ.IR

PROGRESSIVE SUPRANUCLEAR PALSY. A rare disease that gradually destroys nerve cells in the parts of the brain that control eye movements, breathing, and muscle coordination. The loss of nerve cells causes palsy, or paralysis, that slowly gets worse as the disease progresses. The palsy affects ability to move the eyes, relax the muscles, and control balance.

PROHORMONES. A physiologically inactive precursor of a hormone.

PROJECTILE VOMITING. Vomiting that occurs forcefully such that stomach contents may be ejected from the body in a way that propels expelled contents to a distance.

PROJECTIVE TEST. A type of psychological test that assesses a person's thinking patterns, observational ability, feelings, and attitudes on the basis of responses to ambiguous test materials. It is not intended to diagnose psychiatric disorders.

PROKINETIC. A drug that works to speed up the emptying of the stomach and the motility of the intestines.

PROLACTIN. A hormone produced by the pituitary gland.

PROLACTINOMA. A benign (noncancerous) tumor of the pituitary gland that secretes the hormone prolactin.

PROLAPSED CORD. Pushing of the umbilical cord into the vagina ahead of the baby, cutting off its blood flow.

PROLAPSED UMBILICAL CORD. Occurs when the cord falls into the birth canal, and may even hang out of the mother's vagina. This can cause compression of the cord and lead to decreased oxygen and blood flow to the fetus.

PROLAPSED UTERUS. A uterus that has slipped out of place, sometimes protruding down through the vagina.

PROLIFERATIVE RETINOPATHY. Retinopathy with the growth of new blood vessels (neovascularization).

PRONATION. The lowering or descending of the inner edge of the foot by turning the entire foot outwards.

PROPENSITY. A greater risk for developing a disease.

PROPHYLACTIC. Referring to medications or other treatments given to prevent disease.

PROPHYLACTIC DOSAGE. Giving medications to prevent or protect against diseases.

PROPHYLACTIC MASTECTOMY. Removal of a healthy breast to prevent future breast cancer.

PROPHYLAXIS. A measure designed to preserve health and/or prevent the spread of disease.

PROPRIOCEPTIVE. Pertaining to proprioception, or the awareness of posture, movement, and changes in equilibrium and the knowledge of position, weight, and resistance of objects as they relate to the body.

PROPIONIBACTERIUM ACNES. Skin bacteria that infect sebaceous follicles, causing acne.

PROSECTION. The dissection of a human or animal cadaver by an experienced anatomist in order to instruct students. The term may refer either to the actual performance of the dissection while the students observe the instructor, or to the dissected specimen that is presented to the students for review.

PROSTAGLANDIN. A hormone-like chemical produced in the body that has a variety of effects. Prostaglandins may be responsible for the production of some types of pain and inflammation.

PROSTAGLANDIN ANALOGUE. A class of drugs that are similar in structure and function to prostaglandin.

PROSTATE. The walnut-shaped gland that surrounds the urethra at the neck of the bladder in males and supplies fluid for semen.

PROSTATECTOMY. Performed for the treatment of prostate disease including prostate cancer.

PROSTATE-SPECIFIC ANTIGEN (PSA). A substance that often is produced by cancers of the prostate. It can be detected in a blood test.

PROSTHESIS. An artificial joint, part of a joint, or limb.

PROSTHETIC TOOTH. The final tooth that is held in place by the dental implant anchor.

PROSTHETICS. Mechanical devices that replace missing body parts.

PROSTHETIST. A healthcare professional who is skilled in making and fitting artificial parts (prosthetics) for the human body.

PROSTHODONTIST. A dentist with specialized training in restoring dental function after surgery and making dental prostheses.

PROTEASE INHIBITOR (PI). An antiretroviral drug that interferes with an enzyme required for HIV replication.

PROTEIN. Chains of amino acids that are essential constituents of all living cells and include structural components, enzymes, hormones, and antibodies.

PROTEINURIA. Excess protein in the urine.

PROTHROMBIN. A type of protein called a glycoprotein that is converted to thrombin during the clotting process.

PROTHROMBIN TEST. A common test to measure the amount of time it takes for a patient's blood to clot; measurements are in seconds.

PROTOCOL. A set of guidelines for a patient's therapy; a treatment plan.

PROTOPORPHYRIN. A precursor molecule to the porphyrin molecule.

PROTOPORPHYRIN IX. A protein. The measurement of this protein is useful for the assessment of iron status. Hemoglobin consists of a complex of a protein plus heme. Heme consists of iron plus protoporphyrin IX. Normally, during the course of red blood cell formation, protoporphyrin IX acquires iron, to generate heme, and the heme becomes incorporated into hemoglobin. However, in iron deficiency, protophoryrin IX builds up.

PROTOZOA. Group of extremely small single cell (unicellular) or acellular organisms that are found in moist soil or water. They tend to exist as parasites, living off other life forms.

PROVITAMIN A. Carotenoids such as beta-carotene, alpha-carotene, and beta-cryptoxanthin that are converted to vitamin A in the body.

PROXIMAL TUBULE. The portion of the kidney tubule that lies closest to the point at which fluid from the blood enters the tubule.

PROXY. A person authorized or empowered to act on behalf of another; also, the document or written authorization appointing that person.

PRUNE BELLY SYNDROME (PBS). A genetic disorder associated with abnormalities of human chromosomes 18 and 21. Male infants with PBS often have cryptorchidism along with other defects of the genitals and urinary tract. PBS is also known as triad syndrome and Eagle-Barrett syndrome.

PRURICEPTORS. Nerve endings specialized to perceive itching sensations.

PRURITUS. The medical term for itching.

PRUSSIAN BLUE. The common name of potassium ferric hexacyanoferrate, a compound approved in the United States for treatment of thallium poisoning. Prussian blue gets its name from the fact that it was first used by artists in 1704 as a dark blue pigment for oil paints. It has also been used in laundry bluing and fabric printing.

PSEUDOANEURYSM. A dilation of a blood vessel that resembles an aneurysm.

PSEUDODEMENTIA. Depression with symptoms resembling those of dementia. The term "dementia of depression" is now preferred.

PSEUDOGYNECOMASTIA. Enlargement of the male breast caused solely by fat accumulation. It is also called lipomastia.

PSEUDOMEMBRANOUS COLITIS. A potentially life-threatening inflammation of the colon, caused by a toxin released by the Clostridium difficile bacterium that multiplies rapidly following antibiotic treatment.

PSEUDOPHAKIC BULLOUS KERATOPATHY. Painful swelling of the cornea occasionally occurring after surgery to implant an artificial lens in place of a lens affected by cataract.

PSEUDOXANTHOMA ELASTICUM. A hereditary disorder of the connective, or elastic, tissue marked by premature aging and breakdown of the skin and degeneration of the arteries that leads to hemorrhages.

PSORALEN. A family of photosensitizing chemicals that can be found in lemons, celery, and other plants. Chemically synthesized versions are used to augment the effects of UVA light treatments.

PSORIASIS. A skin disease in which people have itchy, scaly, red patches on the skin.

PSORIATIC ARTHRITIS. Inflammation of the joints that develops in some psoriasis patients.

PSORIATIC ARTHRITIS MUTILANS. A severe form of psoriatic arthritis that destroys the joints of the fingers and toes and causes the bones to fuse, leaving patients with gnarled and club-like hands and feet.

PSYCHIATRIC. Relating to psychiatry.

PSYCHIATRIC NURSING. The nursing specialty concerned with the prevention and treatment of mental disorders and their consequences.

PSYCHIATRIST. A medical doctor who has completed specialized training in the diagnosis and treatment of mental illness. Psychiatrists can diagnose mental illnesses, provide mental health counseling, and prescribe medications.

WWW.BOOKBAZ.IR

PSYCHIC NUMBING. An inability to respond emotionally with normal intensity to people or situations; this numbing affects positive as well as negative emotions.

PSYCHOACTIVE. Referring to any substance that crosses the blood-brain barrier and acts primarily upon the central nervous system, leading to changes in mood, perception, thinking, feeling, or behavior.

PSYCHOACTIVE DRUG. Any drug that affects the mind or behavior. There are five main classes of psychoactive drugs: opiates and opioids (e.g. heroin and methadone); stimulants (e.g. cocaine, nicotine), depressants (e.g. tranquilizers, antipsychotics, alcohol), hallucinogens (e.g. LSD), and marijuana and hashish.

PSYCHODYNAMIC PSYCHOTHERAPY. A less intensive form of insight-oriented therapy than psychoanalysis that typically involves greater interaction between therapist and patient than classical psychoanalysis.

PSYCHODYNAMIC THERAPY. A therapy technique that assumes improper or unwanted behavior is caused by unconscious, internal conflicts and focuses on gaining insight into these motivations.

PSYCHOGENIC. Referring to a disorder associated with mental or emotional conflict. At one time most stuttering was considered psychogenic, but recent research indicates that psychogenic stuttering is the least common form.

PSYCHOLOGICAL. Pertaining to the mind, its mental processes, and its emotional makeup.

PSYCHOLOGICAL TESTS. Written, verbal, or visual tasks that assess psychological functioning, intelligence, and/or personality traits.

PSYCHOLOGIST. A mental health professional who treats mental and behavioral disorders by support and insight to encourage healthy behavior patterns and personality growth. Psychologists also study the brain, behavior, emotions, and learning.

PSYCHOMETRIC. A branch of psychology that deals with measurement of mental capacities, processes, and traits.

PSYCHOMOTOR AGITATION. Disturbed physical and mental processes (e.g., fidgeting, wringing of hands, racing thoughts); a symptom of major depressive disorder.

PSYCHOMOTOR RETARDATION. Slowed physical and mental processes (e.g., slowed thinking, walking, and talking); a symptom of major depressive disorder.

PSYCHOPATHOLOGY. A mental disorder or illness, such as schizophrenia, personality disorder, or major depressive disorder.

PSYCHOSIS. A serious mental disorder characterized by defective or lost contact with reality often with hallucinations or delusions.

PSYCHOSOCIAL. A term that refers to the emotional and social aspects of psychological disorders.

PSYCHOSOMATIC. Referring to physical symptoms that are caused or significantly influenced by emotional factors. Some doctors regard couvade syndrome as a psychosomatic condition.

PSYCHOSURGERY. Brain surgery performed to alleviate chronic psychological conditions such as obsessive-compulsive disorder (OCD), depression, and bipolar disorder.

PSYCHOTHERAPY. The treatment of mental and behavioral disorders by support and insight to encourage healthy behavior patterns and personality growth.

PSYCHOTIC DISORDER. A mental disorder characterized by delusions, hallucinations, or other symptoms of lack of contact with reality. The schizophrenia are psychotic disorders.

PSYLLIUM HYDROPHILIC MUCILLOID. A plant material contained in some laxatives.

PTEROPUS. A genus of at least 60 tropical and subtropical bats, commonly called fruit bats or flying foxes, that are the largest bats in the world and include the reservoirs for nipah and hendra viruses.

PUBERTY. The period of life in which boys' and girls' sexual organs begin to reach maturity and the ability to reproduce begins.

PUBIS. The front portion of the pelvis located in the anterior abdomen.

PULMONARY. Pertaining to the lungs.

PULMONARY ARTERY. An artery that carries blood from the heart to the lungs.

PULMONARY EDEMA. A problem caused when fluid backs up into the veins of the lungs. Increased pressure in these veins forces fluid out of the vein and into the air spaces (alveoli). This interferes with the exchange of oxygen and carbon dioxide in the alveoli.

PULMONARY EMBOLISM. Blockage of a pulmonary artery by a blood clot or foreign matter.

PULMONARY FIBROSIS. Scarring of lung tissue.

PULMONARY FUNCTION TEST. A test that measures the capacity and function of the lungs as well as the blood's ability to carry oxygen. During the test, the patient breathes into a device called a spirometer.

PULMONARY HYPERTENSION. Abnormally high blood pressure within the pulmonary artery.

PULMONARY NODULE. Also called a lung nodule; a lesion surrounded by normal lung tissue. Nodules may be caused by bacteria, fungi, or a tumor (benign or cancerous).

PULMONARY REHABILITATION. A program that helps patients learn how to breathe easier and improve their quality of life. Pulmonary rehabilitation includes treatment, exercise training, education, and counseling.

PULMONARY SYSTEM. Lungs and respiratory system of the body.

PULMONARY VALVE. The heart valve that separates the right ventricle and the opening into the pulmonary artery.

PULMONARY VEIN ISOLATION. A surgical procedure used to treat atrial fibrillation. During the procedure, a radio frequency probe, microwave probe, or cryoprobe is inserted and, under direct vision, used to create lesion lines in the heart to interrupt the conduction of abnormal impulses.

PULMONIC VALVE. A fold in the pulmonary artery that directs blood to the lungs. It may be transferred to replace a severely diseased aortic valve during heart valve replacement surgery for aortic stenosis.

PULMONOLOGIST. A physician who specializes in caring for people with lung diseases and breathing problems.

PULP. The soft, innermost part of a tooth containing blood and lymph vessels, and nerves.

PULP CHAMBER. The area within the tooth occupied by dental pulp.

PULPITIS. Inflammation of the pulp of a tooth involving the blood vessels and nerves.

PULSE OXIMETRY. A noninvasive test in which a device that clips onto the finger measures the oxygen level in the blood.

PUNCH BIOPSY. A method of obtaining skin samples under local anesthesia using a surgical skin punch.

PUNCTUM. Tiny opening at the inner corners of the upper and lower lids. The area for the beginning of tear drainage.

PUNCTURE. An injury caused by a sharp, narrow object deeply penetrating the skin.

PUPIL. The part of the eye that looks like a black circle in the center of the iris. It is actually an opening through which light passes.

PURIFIED PROTEIN DERIVATIVE (PPD). An extract of tubercle bacilli that is injected into the skin to find out whether a person presently has or has ever had tuberculosis.

PURINE. A white crystalline substance that is one of the building blocks of DNA. Uric acid is produced when purine is broken down in the body.

PURKINJE'S CELLS. Large branching cells of the nervous system.

PURPURA. A skin discoloration of purplish or brownish red spots caused by bleeding from broken capillaries.

PURULENT. Consisting of or containing pus.

PUS. A whitish-yellow material produced by the body in response to a bacterial infection. It consists of tissue fluid and dead white blood cells.

PUSTULE. A small raised pimple or blister-like swelling of the skin that contains pus.

PUSTULOSIS. The presence of pus-filled blisters. Palmar pustolosis refers to the presence of such blisters on the palms of the hands. Plantar pustulosis refers to the presence of such blisters on the soles of the feet.

PUVA. A type of phototherapy that combines the oral or topical photosensitizing chemical psoralen, plus long-wave ultraviolet light-A (UVA).

PYELONEPHRITIS. An inflammation of the kidney itself, usually caused by a bacterial infection. In its most serious form, complications can include high blood pressure (hypertension) and renal failure.

PYELUM. Also called the renal pelvis, a funnel-like dilated proximal portion of the ureter within the kidneys.

PYLORIC SPHINCTER. A broad band of muscle in the pylorus valve at the bottom end of the stomach.

PYLOROPLASTY. Widening of the pyloric canal and any adjacent duodenal structure by means of a longitudinal incision.

WWW.BOOKBAZ.IR

PYLORUS. The valve at the bottom end of the stomach that releases food from the stomach into the intestines.

PYODERMA. A pus-containing bacterial skin infection.

PYOGENIC. Capable of generating pus. *Streptococcus*, *Staphocococcus*, and bowel bacteria are the primary pyogenic organisms.

PYOGENIC ARTHRITIS. Another name for infectious arthritis. Pyogenic means that pus is formed during the disease process.

PYRETHRIN, PYRETHROID. Naturally-occurring insecticide extracted from chrysanthemum flowers. It paralyzes lice so that they cannot feed.

PYREXIA. A medical term denoting fevers.

PYRIDOSTIGMINE BROMIDE (MESTINON). An anticholinesterase drug used in treating myasthenia gravis.

PYRIDOXAL 5′-PHOSPHATE. The active form of pyridoxine or vitamin B_6.

PYROGEN. A chemical circulating in the blood that causes a rise in body temperature.

PYROMANIA. An impulse control disorder in which one sets fires.

Q

Q-FEVER. A disease that is marked by high fever, chills, and muscle pain. It is seen in North America, Europe, and parts of Africa. It may be spread by drinking raw milk or by tick bites.

QI. Basic life energy, according to traditional Chinese medicine.

QRS. A pattern seen in an electrocardiogram that indicates the pulses in a heartbeat and their duration. Variations from a normal QRS pattern indicate heart disease.

Q-SWITCHED LASER (QSL). The type of laser generally used for tattoo removal.

QUADRANTECTOMY. Removal of a quadrant, or about a quarter of the breast.

QUADRICEPS MUSCLES. A set of four muscles on each leg located at the front of the thigh. The quadriceps straighten the knee and are used every time a person takes a step.

QUADRICEPS, HIP FLEXORS, HAMSTRINGS. Major muscles in the thigh area which affect knee mechanics.

QUADRIPLEGIA. Paralysis of all four limbs.

QUADRIVALENT VACCINE. A vaccine that protects against four pathogens.

QUANTIFIABLE. Can be expressed as a number. The results of quantifiable psychological tests can be translated into numerical values, or scores.

QUÉTELET INDEX. The original name of the body mass index, after the Belgian statistician who devised it between 1830 and 1850.

QUININE. One of the first treatments for malaria, quinine is a natural product made from the bark of the Cinchona tree. It was popular until being superseded by the development of chloroquine in the 1940s. In the wake of widespread chloroquine resistance, however, it has become popular again. Quinine, or its close relative quinidine, can be given intravenously to treat severe *Falciparum* malaria.

QUINOLONES. A group of synthetic antibacterial drugs originally derived from quinine. Nalidixic acid is the first quinolone that was approved for clinical use.

QV. Quantum vacuum, a theory coined by physicists, which defines the interactions of energy that combine to form reality.

R

RABIES. A rare but serious disease caused by a virus carried in saliva. It is transmitted when an infected animal bites a person.

RADIAL ARTERY. An artery located in the arm and used for bypass grafts.

RADIAL KERATOTOMY (RK). A surgical procedure involving the use of a diamond-tipped blade to make several spoke-like slits in the peripheral (nonviewing) portion of the cornea to improve the focus of the eye and correct myopia by flattening the cornea.

RADIATION THERAPY. A cancer treatment that uses high-energy rays to kill or weaken cancer cells. Radiation may be delivered externally or internally via surgically implanted pellets.

RADICAL MASTECTOMY. Removal of the breast, chest muscles, axillary lymph nodes, and associated skin and subcutaneous tissue.

RADICAL PROSTATECTOMY. Surgical removal of the entire prostate, a common method of treating prostate cancer.

RADICAL RESECTION. Surgical resection that takes the blood supply and lymph system supplying the organ along with the organ.

RADICULAR. Pain that is caused by the root of a nerve.

RADICULOPATHY. Sometimes referred to as a pinched nerve, it refers to compression of the nerve root—the part of a nerve between vertebrae. This compression causes pain to be perceived in areas to which the nerve leads.

RADIO SURGERY AND RADIOTHERAPY. Used in the treatment of cancerous growths or kidney stones.

RADIO WAVES. Electromagnetic energy of the frequency range corresponding to that used in radio communications, usually 10,000–300 billion cycles per second. Radio waves are the same as visible light, x rays, and all other types of electromagnetic radiation, but are of a higher frequency.

RADIOACTIVE ISOTOPE. One of two or more atoms with the same number of protons but a different number of neutrons with a nuclear composition. In nuclear scanning, radioactive isotopes are used as a diagnostic agent.

RADIOCONTRAST AGENTS. Dyes administered to a patient for the purposes of a radiologic study.

RADIOFREQUENCY ABLATION (RFA). A technique for removing a tumor by heating it with a radiofrequency current passed through a needle electrode.

RADIOGRAPH. The actual picture or film produced by an x-ray study.

RADIOGRAPHICALLY DENSE. Having an abundance of glandular tissue that results in diminished anatomic detail on the mammogram.

RADIOISOTOPE. A radioactive form of a chemical element, which is used in medicine for therapeutic or diagnostic purposes.

RADIOLOGIST. A medical doctor specially trained in radiology (x-ray) interpretation and its use in the diagnosis of diseases and injuries.

RADIONUCLIDE. A substance that emits radiation as it disintegrates.

RADIONUCLIDE BONE SCAN. A test that tells if cancer has spread to the bones.

RADIONUCLIDE SCANNING. Diagnostic test in which a radioactive dye is injected into the bloodstream and photographed to display internal vessels, organs, and tissues.

RADIOPHARMACEUTICAL. A radioactive pharmaceutical or chemical (usually radioactive iodine or cobalt) used for diagnostic or therapeutic purposes.

RADIOSURGERY. Precise delivery of a large dose of radiation to a targeted area within the brain.

RADIOTHERAPY. The use of ionizing radiation, either as x rays or radioactive isotopes, to treat disease.

RADIUS. The shorter and smaller of the two long bones in the forearm.

RANGE OF MOTION (ROM). The range of motion of a joint from full extension to full flexion (bending) measured in degrees like a circle.

RAPID CYCLING. Four or more manic, hypomanic, mixed, or depressive episodes within a 12-month period.

RAPID EYE MOVEMENT (REM) SLEEP. A phase of sleep during which the person's eyes move rapidly beneath the lids. It accounts for 20–25% of sleep time. Dreaming occurs during REM sleep.

RASH. A spotted, pink or red skin eruption that may be accompanied by itching and is caused by disease, contact with an allergen, food ingestion, or drug reaction.

RAYNAUD PHENOMENON/RAYNAUD DISEASE. A condition in which blood flow to the body's tissues is reduced by a malfunction of the nerves that regulate the constriction of blood vessels. When attacks of Raynaud's occur in the absence of other medical conditions, it is called Raynaud disease. When attacks occur as part of a disease (as in scleroderma), it is called Raynaud phenomenon.

REACTIVE STRESS TEST. A positive sign of fetal well being. The FHR rises at least 20 beats per minute above the baseline heart rate for at least 20 seconds, occurring at least twice in a 20-minute period.

REAL-TIME. A type of ultrasound that takes multiple images over time in order to record movement, allowing observations during the scan (rather than having to wait until after the procedure to look at films).

REAL-TIME TELEHEALTH. Telehealth in which a telecommunications link (e.g., telephone, videoconferencing equipment, e-mail) allows for immediate communication. It is also called synchronous telehealth.

REBOUND HEADACHE. A type of primary headache caused by overuse of pain relievers. It is also known as analgesic abuse headache.

RECEPTOR. A molecule, usually a protein, inside or on the surface of a cell that binds a specific chemical

WWW.BOOKBAZ.IR

group or molecule, such as a hormone or growth factor, to initiate a sequence of events.

RECESSIVE TRAIT. An inherited trait that is outwardly obvious only when two copies of the gene for that trait are present; an individual displaying a recessive trait must have inherited one copy of the defective gene from each parent.

RECIPIENT. The person who receives the donated blood marrow.

RECOMBINANT PROTEIN. A manipulated or modified form of a protein that results in the ability to produce the modified protein on a large scale.

RECOMMENDED DIETARY ALLOWANCE (RDA). The quantities of nutrients of the diet that are required to maintain human health. RDAs are established by the Food and Nutrition Board of the National Academy of Sciences and may be revised every few years.

RECOMPRESSION. Restoring the elevated pressure of the diving environment to treat gas embolism by decreasing bubble size.

RECTAL PROLAPSE. Protrusion of the rectal mucous membrane through the anus.

RECTOCELE. Bulging of the rectum into the vaginal wall.

RECTUM. The last part of the intestine. Stool passes through the rectum and out through the anal opening.

RECURRENCE. The return of an active herpes infection following a period of latency.

RECURRENT ABDOMINAL PAIN (RAP). Functional abdominal pain; stomachaches in children that recur at least once a month and that are not caused by an underlying medical condition.

RECURRENT CORNEAL EROSION (RCE). Repeated erosion of the cornea. May be a result of inadequate healing of a previous abrasion.

RECURRENT LARYNGEAL NERVE. A nerve that lies very near the parathyroid glands, and serves the larynx or voice box.

RECURRENT ULCER. Peptic ulcers that flare up after healing. They may be caused a *helicobacter pylori* bacterial infection and are treated with a combination of antibiotics and gastric acid-reducing medications, like proton pump inhibitors.

RED BLOOD CELL (RBC). Hemoglobin-containing blood cells that transport oxygen from the lungs to tissues. In the tissues, the red blood cells exchange their oxygen for carbon dioxide, which is brought back to the lungs to be exhaled.

RED BLOOD CELL INDICES. Measurements that describe the size and hemoglobin content of red blood cells.

RED CELL DISTRIBUTION WIDTH (RDW). A measure of the variation in size of red blood cells.

REDUCE. To restore a part of the body to its normal position or place, as in treating a fracture or dislocation. The repositioning of the bone or body part is called a reduction.

REDUCIBLE HERNIA. A hernia that can be gently pushed back into place or that disappears when the person lies down.

REDUCTION. The restoration of a body part to its original position after displacement, such as the reduction of a fractured bone by bringing ends or fragments back into original alignment. The use of local or general anesthesia usually accompanies a fracture reduction. If performed by outside manipulation only, the reduction is described as closed; if surgery is necessary, it is described as open.

REDUCTION. When a chemical element or compound gains an electron.

REED-STERNBERG CELLS. Cancerous cells that, when present in the body, are indicative of Hodgkin's lymphoma.

REFERRED PAIN. Pain that is experienced in one part of the body but originates in another organ or area. The pain is referred because the nerves that supply the damaged organ enter the spine in the same segment as the nerves that supply the area where the pain is felt.

REFLEX. An involuntary response to a particular stimulus.

REFLEX SEIZURE. Seizure brought on by specific sensory stimuli.

REFLEX SYMPATHETIC DYSTROPHY (RSD). A type of complex regional pain syndrome without identifiable peripheral nerve injury.

REFLEXOLOGY. Belief that reflex areas in the feet correspond to every part of the body, including organs and glands, and that stimulating the correct reflex area can affect the body part.

REFLUX. An abnormal backward or return flow of a fluid.

REFLUX ESOPHAGITIS. Inflammation of the lower esophagus caused by the backflow of stomach contents.

REFRACTION. The turning or bending of light waves as the light passes from one medium or layer to another. In the eye it means the ability of the eye to bend light so that an image is focused onto the retina.

REFRACTIVE ERROR. The inability of the eye to properly focus light due to an irregularly shaped cornea, resulting in blurry vision, nearsightedness, farsightedness, or astigmatism.

REFRACTIVE EYE SURGERY. A general term for surgical procedures that can improve or correct refractive errors by permanently changing the shape of the cornea.

REGENERATIVE MEDICINE. A new branch of medicine that investigates ways to restore damaged tissues or organs by replacing them with new ones derived from the patient's stem cells, or by stimulating the body's own repair mechanisms to heal damaged organs.

REGIONAL ANESTHESIA. Blocking of specific nerve pathways through the injection of an anesthetic agent into a specific area of the body.

REGISTERED DIETITIAN (RD). A health professional who has a bachelor's degree, specializing in foods and nutrition, and in addition, undergoes a period of practical training in a hospital or community setting. Many dietitians further their knowledge by pursuing master's or doctoral degrees. The title "registered dietitian" is protected by law so that only qualified practitioners who have met education qualifications can use that title.

REGISTERED NURSE. A graduate nurse who has passed a state nursing board examination and been registered and licensed to practice nursing.

REGRESSION. In psychology, a return to earlier, usually childish or infantile, patterns of thought or behavior.

REGURGITATE. Thrown or poured back, usually referring to swallowed food coming back up into the throat and mouth.

REGURGITATION. Thrown or poured back, usually referring to swallowed food coming back up into the throat and mouth.

REGURGITATION. Backward flow of blood through a partly closed valve.

REHYDRATION. The restoration of water or fluid to a body that has become dehydrated.

REIKI. A spiritual practice that developed in Japan in the 1920s that is considered a form of energy therapy. Reiki practitioners believe that they can convey healing energy to others through stylized hand positions that can be placed on or near the patient.

REITER'S SYNDROME. A group of symptoms that includes arthritis, inflammation of the urethra, and conjunctivitis, and develops as a late complication of infection with *Shigella flexneri*. The syndrome was first described by a German doctor named Hans Reiter in 1918.

REJECTION. The process in which the immune system attacks foreign tissue such as a transplanted organ.

RELAPSE. A return of the signs and symptoms of an illness.

RELAPSING-REMITTING. A pattern of symptoms of multiple sclerosis in which symptomatic attacks occur that last 24 hours or more, followed by complete or almost complete improvement.

RELAXATION RESPONSE. The human body's response to relaxation techniques, during which metabolism and stress levels decrease and immune response increases.

RELAXATION TECHNIQUE. A technique used to relieve stress. Exercise, biofeedback, hypnosis, and meditation are all effective relaxation tools. Relaxation techniques are used in cognitive-behavioral therapy to teach patients new ways of coping with stressful situations.

REM LATENCY. After a person falls asleep, the amount of time it takes for the first onset of REM sleep.

REMEDY ANTIDOTE. Certain foods, beverages, prescription medications, aromatic compounds, and other environmental elements that counteract the efficacy of homeopathic remedies.

REMISSION. When active symptoms of a chronic disease are absent.

REMODELING. The ongoing process of bone formation and breakdown that results in healthy bone development.

RENAL. Referring to the kidneys.

RENAL AGENESIS. Failure of the fetal kidneys to form. Oligohydramnios usually associated with absence of both kidneys.

WWW.BOOKBAZ.IR

RENAL ARTERY ANEURYSM. An aneurysm relating to, involving, or located in the region of the kidneys.

RENAL ARTERY STENOSIS. Narrowing or constriction of the artery that supplies the kidney with blood.

RENAL CELL CARCINOMA. Cancer of the kidney.

RENAL DISEASE. Kidney disease.

RENAL FAILURE. Disorder characterized by the kidney's inability to filter wastes from the blood. It may be acute (occurring suddenly and usually reversible) or chronic (developing slowly over time as a result of permanent damage).

RENAL ULTRASOUND. A painless and non-invasive procedure in which sound waves are bounced off the kidneys. These sound waves produce a pattern of echoes that are then used by the computer to create pictures of areas inside the kidney (sonograms).

RENIN. An enzyme produced in the kidneys that controls the activation of the hormone angiotensin, which stimulates the adrenal glands to produce aldosterone.

REPERFUSION THERAPY. Restoration of blood flow to an organ or tissue; following a heart attack, quickly opening blocked arteries to reperfuse the heart muscles to minimize damage.

REPETITIVE STRESS INJURY; REPETITIVE STRAIN INJURY (RSI). Any of various musculoskeletal disorders—such as tendonitis or carpal tunnel syndrome—that are caused by cumulative damage to muscles, tendons, ligaments, nerves, or joints from highly repetitive movements, such as of the hand, wrist, arm, or shoulder.

REPRESENTATIVE SAMPLE. A random sample of people that adequately represents the test-taking population in age, gender, race, and socioeconomic standing.

REPRESSION. A unconscious psychological mechanism in which painful or unacceptable ideas, memories, or feelings are removed from conscious awareness or recall.

REPRODUCTIVE ORGANS. The group of organs (including the testes, ovaries, and uterus) whose purpose is to produce a new individual and continue the species.

RESECT. To remove surgically.

RESECTABLE CANCER. A tumor that can be surgically removed.

RESECTION. Removal of a portion, or all, of an organ or other structure.

RESERVOIR. An animal species that harbors a virus, usually without symptoms of infection, and can transmit it to humans, either directly or via a vector.

RESIDUAL VOLUME. The volume of air remaining in the lungs, measured after a maximum expiration.

RESILIENCE. In psychiatry, the ability of a person to respond positively to, or bounce back from, trauma or hardship. Resilience is considered a process of interaction between the person and his or her environment rather than a one-time action.

RESORBED. Absorbed by the body because of lack of function. This happens to the jawbone after tooth loss.

RESORPTION. The removal of old bone from the body.

RESPIRATION. Respiration is the process by which nutrients (specifically sugar, or glucose) and oxygen are taken in to a cell; chemical reactions take place; energy is produce and stored; and carbon dioxide and wastes are given off.

RESPIRATORY. Referring to breathing in and breathing out and the function of the lungs.

RESPIRATORY DISTRESS. A condition in which patients with lung disease are not able to get enough oxygen.

RESPIRATORY DISTRESS SYNDROME. Also known as hyaline membrane disease, this is a condition of premature infants in which the lungs are imperfectly expanded due to a lack of a substance on the lungs that reduces tension.

RESPIRATORY FAILURE. The sudden inability of the lungs to provide normal oxygen delivery or normal carbon dioxide removal.

RESPIRATORY THERAPIST. A health care professional who specializes in assessing, treating, and educating people with lung diseases.

RESPIRATORY THERAPY. The department of any health care facility or agency that provides treatment to patients to maintain or improve their breathing function.

RESPIRATORY TRACT. The air passages from the nose to the air sacs of the lungs, including the pharynx, larynx, trachea, and bronchi.

RESPITE CARE. Temporary care of a patient to provide parents or other caregivers with a period of physical, mental, and emotional rest.

RESTENOSIS. The narrowing of a blood vessel after it has been opened, usually by balloon angioplasty.

RESTLESS LEGS SYNDROME (RLS). A neurological disorder characterized by aching, burning, or creeping sensations in the legs and an urge to move the legs, often resulting in insomnia.

RESTRICTIVE. A type of bariatric surgery that works by limiting the amount of food that the stomach can hold. Vertical banded gastroplasty is a restrictive procedure.

RESUSCITATION. Reviving an unconscious person or restoring breathing.

RETAINER. A fee paid in advance to a doctor, lawyer, or other professional to secure services when needed.

RETENTION TREATMENT STAGE. The passive treatment period following orthodontic treatment, when retainers may be used to stabilize the teeth.

RETICULOCYTE. An early, immature form of a red blood cell. Over time, the reticulocyte develops to become a mature, oxygen-carrying red blood cell.

RETINA. Light-sensitive tissue on the back of the eye that receives images and converts them into nerve impulses to be sent to the brain by way of the optic nerve.

RETINAL AND RETINOIC ACID. Active forms of vitamin A that are produced in the body from precursors in the diet.

RETINAL DETACHMENT. A serious vision disorder in which the light-detecting layer of cells inside the eye (retina) is separated from its normal support tissue and no longer functions properly.

RETINAL HEMORRHAGE. Bleeding in the back of the eye.

RETINOBLASTOMA. A hereditary malignant tumor of the retina that develops during childhood.

RETINOIC ACID. Vitamin A_1 acid, which is used topically to treat acne.

RETINOID. A synthetic vitamin A derivative used in the treatment of a variety of skin disorders.

RETINOL. Preformed vitamin A that is obtained from animal sources in the diet; the form of vitamin A that is used as the standard for determining dietary intake.

RETINOL ACTIVITY EQUIVALENT (RAE). The standard measure for vitamin A; 1 RAE is equal to 1 mcg of retinol, 12 mcg of beta-carotene, 24 mcg of other provitamin A carotenoids, or about 3 IU.

RETINOPATHY OF PREMATURITY. A condition in which the blood vessels in a premature infant's eyes do not develop normally, which can, in some cases, result in blindness.

RETINOSCOPE. An instrument for determining the state of refraction of the eye by illuminating the retina with a mirror.

RETRACTOR. An instrument used during surgery to hold an incision open and pull back underlying layers of tissue.

RETROGRADE. Describes memory loss of information/events prior to the onset of the amnestic disorder.

RETROGRADE EJACULATION. A condition in which the semen spurts backward into the bladder.

RETROGRADE MENSTRUATION. Menstrual flow that travels into the body cavity rather than being expelled through the uterus.

RETROGRADE PYELOGRAM. A pyelography or x-ray technique in which a dye is injected into the kidneys through the ureters.

RETROGRADE PYELOGRAPHY. A test in which dye is injected through a catheter placed with a cystoscope into the ureter to make the lining of the bladder, ureters, and kidneys easier to see on x rays.

RETROPUBIC URETHROPEXY. A generic term for the Burch procedure and its variants that treat mild stress incontinence by stabilizing the urethra with retropubic surgery.

RETROVIRUS. A virus that contains a unique enzyme called reverse transcriptase that allows it to replicate within new host cells.

REVERSE TRANSCRIPTION-POLYMERASE CHAIN REACTION (RT-PCR). A method of polymerase-chain-reaction amplification of nucleic acid sequences that uses RNA as the template for transcribing the corresponding DNA using reverse transcriptase.

REYE'S SYNDROME. A rare but potentially fatal disorder characterized by a rash, vomiting, and liver damage. It is associated with giving aspirin or other salicylates to children recovering from a viral illness.

RH (RHESUS) FACTOR. An antigen present in the red blood cells of 85% of humans. A person with Rh factor is Rh positive (Rh+); a person without it is

WWW.BOOKBAZ.IR

Rh negative (Rh-). The Rh factor was first identified in the blood of a rhesus monkey.

RH BLOOD INCOMPATIBILITY. A blood type problem between mother (who is Rh negative) and baby (who is Rh positive), making the immune system of the mother attack her unborn baby. During delivery of the first pregnancy, the mother's immune system becomes sensitive to the Rh positive blood of the baby. The mother's system may then attack later pregnancies and cause severe illness or death to those babies.

RH BLOOD TYPE. Blood type based on the presence or absence of the D antigen on the red blood cells.

RH NEGATIVE. Lacking the Rh factor, genetically determined antigens in red blood cells that produce immune responses. If an Rh negative woman is pregnant with an Rh positive fetus, her body will produce antibodies against the fetus's blood, causing a disease known as Rh disease. Sensitization to the disease occurs when the women's blood is exposed to the fetus's blood. Rh immune globulin (RhoGAM) is a vaccine that must be given to a woman after an abortion, miscarriage, or prenatal tests in order to prevent sensitization to Rh disease.

RHABDOID. Rod- or wand-shaped, like the first stage of the threadworm larva.

RHABDOMYOLYSIS. The rapid breakdown of skeletal muscle and release into the blood of muscle cell contents.

RHABDOVIRUS. A type of virus named for its rod- or bullet-like shape. The rabies virus belongs to a family of viruses called Rhabdoviridae.

RHEUMATIC DISEASE. A type of disease involving inflammation of muscles, joints, and other tissues.

RHEUMATIC FEVER. An inflammatory illness that can follow strep throat, and could cause heart damage.

RHEUMATIC HEART DISEASE. A condition caused by a streptococcus infection which can result in permanent heart damage.

RHEUMATOID ARTHRITIS. A chronic autoimmune disease characterized by inflammation of multiple joints and crippling pain and stiffness.

RHEUMATOID FACTOR (RF). An autoantibody present in the blood serum of many individuals affected by or at risk for rheumatoid arthritis.

RHEUMATOLOGIST. A physician who specializes in diagnosing and treating autoimmune diseases and diseases of the joints, soft tissues, and connective tissues.

RHEUMATOLOGY. The study of disorders characterized by inflammation, degeneration of connective tissue, and related structures of the body. These disorders are sometimes collectively referred to as rheumatism.

RHINITIS. Inflammation of the mucous membranes of the nose.

RHINOPHYMA. Long-term swelling and overgrowth in skin tissue of the nose that leaves it with a knobby bulb-like look.

RHINOPLASTY. Plastic surgery of the nose to repair or change the shape of the nose.

RHINOVIRUS. A virus that infects the upper respiratory system and causes the common cold.

RHYTHM METHOD. The oldest method of contraception with a very high failure rate, in which partners periodically refrain from having sex during ovulation. Ovulation is predicted on the basis of a woman's previous menstrual cycle.

RHYTIDECTOMY. Wrinkle excision. It is an older, alternative term for a face lift.

RHYTIDES. Very fine wrinkles, often of the face.

RIBAVIRIN. A drug that is used to combat viral infections.

RIBONUCLEIC ACID (RNA). A molecule that helps decode genetic information (DNA) and is necessary for protein synthesis.

RICKETS. A condition caused by the dietary deficiency of vitamin D, calcium, and usually phosphorus, seen primarily in infancy and childhood, and characterized by abnormal bone formation.

RICKETTSIA. A rod-shaped infectious microorganism that can reproduce only inside a living cell. Scrub typhus is a rickettsial disease.

RIGHT-HEART CARDIAC CATHERIZATION. A medical procedure during which a physician threads a catheter into the right side of the heart to measure the blood pressure in the right side of the heart and the pulmonary artery. The right heart's pumping ability can also be evaluated.

ROD. Photoreceptor that is highly sensitive to low levels of light and transmits images in shades of gray.

ROLFING. Developed by Dr. Ida Rolf (1896–1979); a systematic approach to relieving stress patterns and dysfunctions in the body's structure through the manipulation of the highly pliant myofacial (connective) tissue. It

assists the body in reorganizing its major segments into vertical alignment.

ROOT CANAL. The space within a tooth that runs from the pulp chamber to the tip of the root.

ROOT CANAL TREATMENT. The process of removing diseased or damaged pulp from a tooth, then filling and sealing the pulp chamber and root canals.

RORSCHACH TEST. A well-known projective test that requires the patient to describe what he or she sees in each of 10 inkblots. It is named for the Swiss psychiatrist who invented it.

ROSACEA. A chronic skin disease characterized by persistent redness of the skin and periodic outbreaks of pustules, usually affecting the middle third of the face.

ROSE SPOTS. A pinkish rash across the trunk or abdomen that is a classic sign of typhoid fever.

ROTABLATION. A nonsurgical technique for treating diseased arteries in which a special catheter with a diamond-coated tip is guided to the point of narrowing in the artery. The catheter tip spins at high speed and grinds away the blockage or plaque on the artery walls.

ROTAVIRUS. Any virus of the genus *Rotavirus*, some of which cause gastroenteritis.

ROTHMUND-THOMSON SYNDROME. A rare disorder characterized by short stature, early hair loss, skin rashes, and noncancerous abnormalities of the bones. It is a risk factor for osteosarcoma.

ROTOBLATION. A non-surgical technique for treating diseased arteries.

ROULEAUX. The stacking up of red blood cells, caused by extra or abnormal proteins in the blood that decrease the normal distance red cells maintain between each other.

ROUNDWORM. Any round-bodied unsegmented worm as distinguished from a flatworm. Also called a nematode, they look similar to the common earthworm.

RUBELLA. Also known as German measles. When a woman contracts rubella during pregnancy, her developing infant may be damaged. One of the problems that may result is autism.

RUPTURE. Severing of the aorta, allowing blood to spill out into the body instead of being carried by the blood vessels.

S

SACCULAR ANEURYSM. A type of aneurysm that resembles a small sack of blood attached to the outer surface of a blood vessel by a thin neck.

SACROCOCCYGEAL TERATOMA (SCT). A tumor occurring at the base of the fetus's tailbone.

SACRUM. The triangle-shaped bone located between the fifth lumbar vertebra and the coccyx that consists of five vertebrae fused together. The sacrum joins on each side with the bones of the pelvis.

SALICYLATES. A group of drugs that includes aspirin and related compounds. Salicylates are used to relieve pain, reduce inflammation, and lower fever.

SALICYLIC ACID. An agent prescribed in the treatment of hyperkeratotic skin conditions and fungal infections.

SALICYLIC ACID; SALICYLATE; ACETYLSALICYLATE. Aspirin; medications used as topical disinfectants and orally to relieve pain and fever.

SALINE. A salt solution in water. Normal saline has the same salt concentration as the body, 0.9%.

SALINE SOLUTION. A salt solution in water. Normal saline has the same salt concentration as the body, 0.9%.

SALIVARY DUCT. Tube through which saliva is carried from the salivary gland to the mouth.

SALIVARY GLAND. Gland in which saliva forms.

SALMONELLOSIS. Food poisoning by bacteria of the genus *Salmonella*, which usually causes severe diarrhea and may be transmitted to the fetus.

SALPINGECTOMY. The surgical removal of a fallopian tube.

SALPINGITIS. Inflammation of the fallopian tube.

SALPINGO-OOPHORECTOMY. Surgical removal of the fallopian tubes and the ovaries.

SALVAGE THERAPY. Treatment measures taken late in the course of a disease after other therapies have failed. It is also known as rescue therapy.

SAMANA. Life sustaining energy of the smaller intestine; the fourth of the five airs of Ayurvedic philosophy; the life force governing side-to-side motion.

SANITATION. The process of keeping drinking water, foods, or any anything else with which people come into contact free of microorganisms such as viruses.

WWW.BOOKBAZ.IR

SAPHENOUS VEIN. A long vein in the thigh or calf commonly used for bypass grafts.

SARCOIDOSIS. A chronic disease with unknown cause that involves formation of nodules in bones, skin, lymph nodes, and lungs.

SARCOMA. A type of cancer that originates from connective tissue such as bone or muscle.

SARCOPLASMIC RETICULUM. A system of tiny tubes located inside muscle cells that allow muscles to contract and relax by alternatively releasing and storing calcium.

SARGRAMOSTIM. A medication made from yeast that stimulates WBC production. It is sold under the trade names Leukine and Prokine.

SATURATED FAT. Fat molecules that contain only single bonds; examples include whole milk, cream, palm and coconut oils, and solid fats such as cheese, butter, and meat.

SCABIES. A contagious parasitic skin disease characterized by intense itching.

SCHEMAS. Fundamental core beliefs or assumptions that are part of the perceptual filter people use to view the world. Cognitive-behavioral therapy seeks to change maladaptive schemas.

SCHEUERMANN'S DISEASE. Juvenile kyphosis due to damaged bone in the spinal vertebrae.

SCHIZOAFFECTIVE DISORDER. Schizophrenic symptoms occurring concurrently with a major depressive or manic episode.

SCHIZOPHRENIA. A debilitating mental illness characterized by delusions, hallucinations, disorganized speech and behavior, and flattened affect (i.e., a lack of emotions) that seriously hampers normal functioning.

SCHIZOPHRENIFORM DISORDER. A short-term variation of schizophrenia that has a total duration of one to six months.

SCHWANNOMA. A tumor derived from the cells of the myelin sheath that surrounds many nerve cells.

SCIATICA. Pain that radiates along the sciatic nerve, extending from the buttock down the leg to the foot.

SCINTIGRAM. A nuclear angiogram; a scintigram involves injection of a radioactive substance into the patient's circulatory system. As the substance travels through the body, a special scanning camera takes pictures.

SCINTIGRAPHY. A test used in nuclear medicine to detect abnormalities in the process of bone remodeling. Also called a bone scan, the test involves injecting the patient with radioactive technetium and then scanning the body with a gamma camera. Scintigraphy should not be confused with bone density tests.

SCINTILLATION OR GAMMA CAMERA. A camera, somewhat like an x-ray machine, used to photograph internal organs after the patient has been injected with a radioactive material.

SCLERA. The tough, fibrous, white outer protective covering that surrounds the eye.

SCLERODERMA. A disease that first affects the skin and later affects certain internal organs. The first symptoms are the hardening, thickening, and shrinking of the skin.

SCLEROSANT. An irritating solution that stops bleeding by hardening the blood or vein it is injected into.

SCLEROSIS. The process by which an irritating material is placed in the pleural space in order to inflame the pleural membranes and cause them to stick together, eliminating the pleural space and recurrent effusions.

SCOLIOMETER. A tool for measuring trunk asymmetry; it includes a bubble level and angle measure.

SCOLIOSIS. An abnormal, side-to-side curvature of the spine.

SCOTOMA. An area of lost or depressed vision within the visual field surrounded by an area of normal vision. Survivors of retinoblastoma frequently develop scotomas.

SCREEN. In medicine, any test or technique used to detect patients with a high likelihood of having a specific disease, or to detect one or more substances in body fluids or tissues.

SCROTUM. The external pouch containing the male reproductive glands (testes) and part of the spermatic cord.

SCURVY. A nutritional disorder that causes skin bruising and hemorrhages.

SEALANT. A thin plastic substance that is painted over teeth as an anticavity measure to seal out food particles and acids produced by bacteria.

SEALED RADIOACTIVE SOURCES. A radioactive source contained or sealed within a ribbon, wire, needle, balloon, tube, or catheter.

SEASONAL AFFECTIVE DISORDER (SAD). A mood disorder characterized by depression, weight gain, and sleepiness during the winter months. An estimated 4–6% of the population of Canada and the northern United States suffers from SAD.

SEBACEOUS FOLLICLES. Structures in the skin that contain oil-producing glands and hair follicles and which give rise acne.

SEBACEOUS GLANDS. Tiny structures in the skin that produce oil (sebum). If they become plugged, sebum collects inside and forms a nurturing place for germs to grow.

SEBUM. An oily or waxy substance secreted by certain glands in the skin that protects hair and skin against fungi and some bacteria.

SECOND SPACE. The extracellular fluid in the body (ECF).

SECONDARY CARE. Health care provided by specialist physicians and other healthcare providers (physical therapists, respiratory therapists, etc.) who do not usually have the initial contact with patients. Secondary care also includes acute care provided in hospital emergency departments.

SECONDARY GAIN. The social, occupational, or interpersonal advantages that a patient derives from symptoms. A patient's being relieved of his or her share of household chores by other family members would be an example of secondary gain.

SECONDARY INFECTION. Illness caused by new bacteria, viruses, or fungi becoming established in the wake of an initial infection.

SECONDARY POLYCYTHEMIA. Secondary polycythemia occurs when the excess of red blood cells is caused by a condition other than polycythemia vera. For example, when low levels of oxygen in the blood stimulate the bone marrow to produce more red blood cells, as in chronic lung disease.

SECONDARY PROGRESSIVE. A pattern of symptoms of multiple sclerosis in which there are relapses and remissions, followed by more steady progression of symptoms.

SECRETION. A substance, such as saliva or mucus, that is produced and given off by a cell or a gland.

SEDATIVE. Medicine that has a calming effect and may be used to treat nervousness or restlessness.

SEDENTARY. Inactivity and lack of exercise; a lifestyle that is a major risk factor for becoming overweight or obese and developing chronic diseases.

SEITAN. The Japanese name for a meat substitute made of wheat gluten. Some vegans prefer seitan to tofu because its texture is stringier and resembles that of meat.

SEIZURE. A sudden attack, spasm, or convulsion.

SELECTIVE ESTROGEN RECEPTOR MODULATOR (SERM). A drug such as tamoxifen that interferes with the binding of estrogen to its receptor; used to prevent and treat breast cancer.

SELECTIVE REDUCTION. Typically referred to in cases of multifetal pregnancy, when one or more fetuses are aborted to preserve the viability of the remaining fetuses and decrease health risks to the mother.

SELECTIVE SEROTONIN REUPTAKE INHIBITORS (SSRIS). A class of antidepressants that works by blocking the reabsorption of serotonin by brain cells, raising the level of the chemical in the brain.

SELENIUM. A mineral needed in extremely small quantities by the body. Large amounts can be very toxic.

SELF-LIMITED. A disease that runs its course without the need for professional medical treatment.

SEMEN. The thick whitish liquid released from the penis during sexual intercourse. It contains sperm and other secretions.

SEMICIRCULAR CANALS. Structures of the inner ear that help in maintaining balance.

SENESCENCE. Aging.

SENSITIVITY. A test's ability to detect all cases of a disease.

SENSITIVITY TEST. A test that determines which antibiotics will kill the bacteria isolated from a culture.

SENSORINEURAL DEAFNESS. Hearing loss due to the inability to convert sound from vibration to electrical signals. Often involves defects in the function of cochlear hair cells.

SENSORINEURAL HEARING LOSS. Hearing loss caused by damage to the nerves or parts of the inner ear governing the sense of hearing.

SENSORY. Refers to peripheral nerves that transmit information from the senses to the brain.

SENSORY AWARENESS. Bringing attention to the sensations of tension and/or release in the muscles.

SENSORY DEPRIVATION. A situation where an individual finds himself in an environment without

WWW.BOOKBAZ.IR

sensory cues. Also, (used here) the act of shutting one's senses off to outside sensory stimuli to achieve hallucinatory experiences and/or to observe the psychological results.

SENSORY INTEGRATION DYSFUNCTION. A neurological disorder in which a person has trouble processing and integrating all the information relayed to the brain by the various senses. Some researchers think that it is a possible cause of selective mutism.

SENSORY NERVES. Sensory or afferent nerves carry impulses of sensation from the periphery or outward parts of the body to the brain. Sensations include feelings, impressions, and awareness of the state of the body.

SENTINEL LYMPH NODE. The first lymph node to receive lymph fluid from a tumor. If the sentinel node is cancer-free, then it is likely that the cancerous cells have not metastasized.

SENTINEL NODE BIOPSY. A newer procedure performed in order to determine whether breast cancer has spread to auxiliary (underarm) lymph nodes. A blue radioactive tracer and/or blue dye is injected into the area of the breast tumor. The lymphatic vessels carry the dye or radioactive material, to a "sentinel node". This sentinel node is thought to be the first lymph node receiving fluid from the tumor and the one most likely to contain cancer cells if the cancer has spread. Only if the sentinel node contains cancer cells are more lymph nodes removed.

SEPSIS. Blood poisoning; a systemic or body-wide infection.

SEPTAL. Relating to the septum, the thin muscle wall dividing the right and left sides of the heart. Holes in the septum are called septal defects.

SEPTAL DEFECTS. Openings in the septum, the muscular wall separating the right and left sides of the heart. Atrial septal defects are openings between the two upper heart chambers and ventricular septal defects are openings between the two lower heart chambers.

SEPTAL HEMATOMA. A mass of extravasated blood that is confined within the nasal septum.

SEPTIC. Referring to the presence of infection.

SEPTIC ARTHRITIS. Severe sepsis with persistent low blood pressure despite fluid resuscitation and resulting inadequate tissue perfusion. The mortality rate of septic shock is 25–50%.

SEPTIC SHOCK. Severe sepsis with persistent low blood pressure despite fluid resuscitation and resulting inadequate tissue perfusion. The mortality rate of septic shock is 25–50%.

SEPTICEMIA. The presence of bacteria and their toxins in the bloodstream. Septicemia is sometimes called blood poisoning.

SEPTUM. The muscular wall that separates the two sides of the heart; an opening in the septum that allows blood to flow from one side to the other is called a septal defect.

SEPTUM (PLURAL, SEPTA). The partition of bone and cartilage in the nose that separates the two nostrils.

SEQUELA (PLURAL, SEQUELAE). In medicine, a pathological condition resulting from a disease, injury, or other trauma.

SEQUESTRATION. A process in which the spleen withdraws blood cells from the circulation and stores them.

SEQUESTRATION AND MARGINATION. The removal of neutrophils from circulating blood by cell changes that trap them in the lungs and spleen.

SERIAL CASTING. A series of casts designed to gradually move a limb into a more functional position.

SERIAL MEASUREMENTS. A series of measurements looking for an increase or decrease over time.

SERIAL MONITORING. Monitoring of results of several blood tests over time to detect a pattern of increasing, decreasing, or unchanging values in the blood.

SERIAL X RAYS. A number of x rays performed at set times in the disease progression or treatment intervals. The radiographs will be compared to one another to track changes.

SEROCONVERSION. The development of specific detectable antibodies in a patient's blood serum as a result of infection or immunization.

SEROLOGICAL TESTS. Tests of immune function that are performed using the clear yellow liquid part of blood.

SEROLOGY. The analysis of the contents and properties of blood serum.

SEROSITIS. Inflammation of a serosal membrane. Polyserositis refers to the inflammation of two or more serosal membranes.

SEROTONIN. 5-Hydroxytryptamine; a substance that occurs throughout the body with numerous

effects including neurotransmission. Inadequate amounts of serotonin are implicated in some forms of depression.

SEROTONIN DOPAMINE ANTAGONIST (SDA). The newer second-generation antipsychotic drugs, also called atypical antipsychotics. SDAs include clozapine (Clozaril), risperidone (Risperdal), and olanzapine (Zyprexa).

SEROTONIN SYNDROME. A group of symptoms caused by severely elevated serotonin levels in the body.

SEROTYPE. A bacterial strain distinguished from other bacteria of the same species by its particular antigens (bacterial molecules that react with specific antibodies).

SERTRALINE. An SSRI that is used to treat mental depression and a variety of other disorders.

SERUM. The part of human blood that remains liquid when blood cells form a clot. Human blood serum is clear light yellow in color.

SERUM GASTRIN TEST. A laboratory test that is performed on a blood sample to determine that level of the hormone gastrin. High levels of gastrin indicate the presence a duodenal ulcer or a gastrinoma.

SERUM REAGENTS. Serum is fluid, or the fluid portion of the blood retained after removal of the blood cells and fibrin clot. Reagents are substances added to the serum to produce a chemical reaction.

SERUM SICKNESS. An inflammatory reaction in humans to proteins in serum derived from animal sources that contain polyclonal antibodies. It develops within four to 10 days after exposure and is characterized by fever, joint pain, itching, rashes, low blood pressure, an enlarged spleen, and protein and blood in the urine.

SEVERE ACUTE RESPIRATORY SYNDROME (SARS). A serious infectious disease caused by a coronavirus that was the first emergent disease of the twenty-first century, arising from transmission events between animals and humans in Chinese markets.

SEX HORMONES. Hormones that are responsible for sexual characteristics and reproductive functioning.

SEX-LINKED. Refers to genes or traits carried on one of the sex chromosomes, usually the X.

SEX-LINKED GENETIC DISORDER. A disease or disorder caused by a gene mutation located on the X (female) or Y (male) chromosome.

SEXUAL ABUSE. When an individual is forced to engage in sexual activity by use of threats or other fear tactics, or instances in which an individual is physically unable to refuse.

SEXUAL ANHEDONIA. The inability to experience sexual pleasure.

SEXUAL AROUSAL DISORDER. The inhibition of the general arousal aspect of sexual response.

SEXUAL ASSAULT NURSE EXAMINER (SANE). A registered nurse who is trained to collect and document evidence from a sexual assault victim, evaluate and treat for STDs and pregnancy, and refer victims to follow-up medical care and counseling.

SEXUAL TOURISM. The practice of traveling to other countries for the purpose of paid sexual encounters.

SEXUALLY TRANSMITTED DISEASE (STD). An infectious disease that is transmitted through sexual activity.

SÉZARY SYNDROME. A leukemic phase of CTCL that develops in some patients, characterized by the appearance of malignant T cells in the peripheral blood and sometimes in the lymph nodes. The syndrome is named for Alfred Sézary (1880-1956), a French dermatologist.

SHAKEN BABY SYNDROME (SBS). A severe form of TBI resulting from shaking an infant or small child forcefully enough to cause the brain to jar against the skull.

SHARED PSYCHOTIC DISORDER. Also known as *folie à deux*, shared psychotic disorder is an uncommon disorder in which the same delusion is shared by two or more individuals.

SHAVE BIOPSY. A method of removing a sample of skin lesion so it can be examined by a pathologist. A scalpel or razor blade is held parallel to the skin's surface and is used to slice the lesion at its base.

SHEAR. Motion that occurs when two surfaces move in opposite directions.

SHEEP BLOOD AGAR PLATE. A petri dish filled with a nutrient gel containing red blood cells that is used to detect the presence of streptococcal bacteria in a throat culture. Streptococcal bacteria will lyse or break the red blood cells, leaving a clear spot around the bacterial colony.

SHIATSU. Japanese form of acupressure massage.

SHIGA TOXIN-PRODUCING *E. COLI* (STEC). Strains of the common, normally harmless, intestinal bacteria

WWW.BOOKBAZ.IR

Escherichia coli that produce Shiga toxin, causing serious food poisoning; *E. coli* O157:H7 is the most commonly identified STEC in North America.

SHIN SPLINTS. Painful injury and inflammation of the tibia and toe extensor muscles or their fasciae from repeated minor trauma such as running on a hard surface.

SHINGLES. A painful rash with blisters that appears along the course of a nerve. It is caused by infection with herpes zoster virus.

SHOCK. A condition in which the amount of blood circulating in the body is inadequate to meet the body's needs. Shock can be caused by certain diseases, serious injury, or blood loss.

SHOCK WAVE THERAPY. A method of treating tennis elbow and other musculoskeletal injuries that involves directing bursts of high-pressure sound waves at the affected area.

SHORT BOWEL SYNDROME. A condition in which the bowel is not as long as normal, either because of surgery or because of a congenital defect. Because the bowel has less surface area to absorb nutrients, it can result in malabsorption syndrome.

SHUNT. A passageway (or an artificially created passageway) that diverts blood flow from one main route to another.

SIALOGOGUE. A medication given to increase the flow of saliva.

SICK BUILDING SYNDROME. An illness related to MCS in which a person develops symptoms in response to chronic exposure to airborne environmental chemicals found in a tightly sealed building.

SICKLE CELL. A red blood cell that has assumed an elongated shape due to the presence of hemoglobin S.

SICKLE CELL ANEMIA. An inherited disorder in which red blood cells contain an abnormal form of hemoglobin, a protein that carries oxygen. The abnormal form of hemoglobin causes the red cells to become sickle- or crescent-shaped. The misshapen cells may clog blood vessels, preventing oxygen from reaching tissues and leading to pain, blood clots and other problems. Sickle cell anemia is most common in people of African descent and in people from Italy, Greece, India, and the Middle East.

SICKLE CELL DISEASE. An inherited disorder in which red blood cells contain an abnormal form of hemoglobin, a protein that carries oxygen. The abnormal form of hemoglobin causes the red cells to become sickle- or crescent-shaped. The misshapen cells may clog blood vessels, preventing oxygen from reaching tissues and leading to pain, blood clots and other problems. Sickle cell anemia is most common in people of African descent and in people from Italy, Greece, India, and the Middle East.

SIDEROBLASTIC ANEMIA. A disorder in which the body has adequate iron but is unable to incorporate it into hemoglobin.

SIDEROPHILIN. Another name for transferrin.

SIDESTREAM SMOKE. The smoke that is emitted from the burning end of a cigarette or cigar or that comes from the end of a pipe. Along with exhaled smoke, it is a constituent of second-hand smoke.

SIGMOID. The S-shaped curve of the large intestine where the colon joins the rectum.

SIGMOID COLON. The final portion of the large intestine that empties into the rectum.

SIGMOIDOSCOPY. A procedure in which a thin, flexible, lighted instrument, called a sigmoidoscope, is used to visually examine the lower part of the large intestine.

SILENT REFLUX. An acid reflux problem that does not have marked symptoms but can cause chronic, recurrent respiratory symptoms much like asthma.

SILICA. A substance (silicon dioxide) occurring in quartz sand, flint, and agate. It is used in making glass, scouring and grinding powders, pottery, etc.

SILICOSIS. A progressive disease that results in impairment of lung function and is caused by inhalation of dust containing silica.

SIMPLE CARBOHYDRATES. Sugar molecules of one or two units (monosaccharides and disaccharides, respectively), such as glucose, fructose, lactose, and sucrose.

SINGLET OXYGEN. A highly reactive form of the oxygen molecule (O_2) formed during PDT that helps to destroy cancer cells by attacking their cell membranes.

SINGLETON. A singleton is a fetus that develops alone in the uterus.

SINUS. In the context of wound management, a narrow hollow in the body extending from an infected area to the surface of the skin.

SINUS TRACT. A narrow, elongated channel in the body that allows the escape of fluid.

SINUSES. The nasal sinuses, air-filled cavities surrounding the eyes and nose, like the nose itself are lined with mucus-producing membranes. They provide cleansing to the nose, resonance to the voice, and structure to the face.

SINUSITIS. Inflammation of the paranasal sinuses because of allergic reactions or viral, bacterial, or functional infections.

SITZ BATH. A warm bath in which just the buttocks and genital area soak in water; used to reduce pain and aid healing in the genital area.

SJÖGREN'S SYNDROME. An autoimmune disorder in which the body's immune system attacks the glands that produce saliva and tears.

SKELETAL MUSCLE. Muscles that move the skeleton. All of the muscles under voluntary control are skeletal muscles.

SKENE'S GLANDS. These are the glands of the female urethra.

SKIN APPENDAGES. Structures related to the integument such as hair follicles and sweat glands.

SKIN CONTRACTURE. A permanent tightening of the skin that prevents normal movement of the associated body part and that can cause permanent deformity. A contracture develops when the normally elastic connective tissues are replaced by inelastic fibrous tissue. This makes the affected area resistant to stretching and prevents normal movement.

SKIN GRAFTING. A technique in which a piece of healthy skin from the patient's body (or a donor's) is used to cover another part of the patient's body that has lost its skin.

SKIN HEMATOMA. Blood from a broken blood vessel that has accumulated under the skin.

SKIN TAG. A small outgrowth of skin tissue that may be smooth or irregular, flesh-colored and benign.

SKIN-SPARING MASTECTOMY. Removal of the breast tissue, leaving the skin intact for breast reconstruction.

SLEEP APNEA. A sleep disorder in which breathing stop briefly then resumes on its own. These pauses can occur many times each night, resulting in poor quality sleep.

SLEEP DISORDER. Any disorder that keep a person from falling asleep or staying asleep.

SLEEP LATENCY. The amount of time that it takes to fall asleep. Sleep latency is measured in minutes and is important in diagnosing depression.

SLEEP PARALYSIS. An abnormal episode of sleep in which the patient cannot move for a few minutes, usually occurring on falling asleep or waking up. Often found in patients with narcolepsy.

SLIT LAMP. A microscope that projects a linear slit beam of light onto the eye; allows viewing of the conjunctiva, cornea, iris, aqueous humor, lens, and eyelid.

SMALL BOWEL OBSTRUCTION (SBO). An obstruction of the small intestine that prevents the free passage of material; sometimes caused by postoperative adhesions.

SMALL BUSINESS HEALTH OPTIONS PROGRAM (SHOP). State systems under the PPACA through which small businesses can compare and purchase health insurance for their employees.

SMALL INTESTINE. Consists of three sections: duodenum (nearest the stomach), jejunum, and ileum (nearest the colon or large intestine). Different nutrients are absorbed in different sections of the small intestine.

SMALL-FOR-GESTATIONAL-AGE (SGA). A term used to describe newborns who are below the tenth percentile in height or weight for their estimated gestational age. The gestational age is based upon the date of the mother's last menstrual period. SGA is one of the symptoms of TORCH syndrome.

SMALLPOX. A highly contagious viral disease characterized by fever, weakness, and skin eruption with pustules that form scabs that slough off leaving scars.

SMEAR. A specimen prepared for microscopic study by spreading the material across a slide and treating it with a specific stain.

SMEAR LAYER. A layer of organic and inorganic material produced on teeth by dental instrumentation that may also contain bacteria and their by-products.

SMOOTH MUSCLES. Muscles that surround the linings of the digestive system, airways, and circulatory system.

SOCIAL MEDIA. A general term for both Web-based and mobile technologies that facilitate social (as distinct from commercial or academic) interaction online.

SOCIAL PHOBIA. Fear of being judged or ridiculed by others; fear of being embarrassed in public.

WWW.BOOKBAZ.IR

SOCIALIZATION. The process through which a person learns his or her roles in society. It includes the society's customs, traditions, and professional roles as well as gender roles.

SOFT PALATE. The structure at the roof of the mouth that separates the mouth and the pharynx.

SOLAR LENTIGINES. Spots appearing on the epidermis due to repeated exposure of the skin to ultraviolet rays, either from the sun or from sunbed tanning. Also called age spots or liver spots.

SOLUTE. Solid substances that are dissolved in liquid in order to make a solution.

SOLUTION-FOCUSED THERAPY. A type of therapy that involves concrete goals and an emphasis on future direction rather than past experiences.

SOMATIC CELLS. All the cells of the body with the exception of the egg and sperm cells.

SOMATIZATION. A chronic condition in which psychological stresses are converted into physical symptoms that interfere with work and relationships. Lower back pain is a frequent complaint of patients with somatization disorder.

SOMATIZATION DISORDER. A chronic condition in which psychological stresses are converted into physical symptoms that interfere with work and relationships. Lower back pain is a frequent complaint of patients with somatization disorder.

SOMATOFORM DISORDER. A category of psychiatric disorder characterized by physical complaints that appear to be medical in origin but that cannot be explained in terms of a physical disease, the results of substance abuse, or by another mental disorder.

SOMNAMBULISM. Another term for sleepwalking.

SONOGRAM. The picture formed by the pattern of echoes from an ultra sound.

SONOGRAPHER. A technologist or physician who uses an ultrasound unit to take ultrasound images of patients.

SORE. An open wound, bruise, or lesion on the skin.

SPACE MAINTAINER. An orthodontic appliance that is worn to prevent adjacent teeth from moving into the space left by an unerupted or prematurely lost tooth.

SPASM. Sudden, involuntary tensing of a muscle or a group of muscles.

SPASTIC. A condition in which the muscles are rigid, posture may be abnormal, and fine motor control is impaired.

SPASTICITY. Increased muscle tone, or stiffness, which leads to uncontrolled, awkward movements.

SPECIFIC GRAVITY. The ratio of the weight of a body fluid when compared with water.

SPECIFICITY. A test's ability to detect only the disease in question.

SPECULUM. An instrument for enlarging the opening of any canal or cavity in order to facilitate inspection of its interior.

SPEECH-LANGUAGE PATHOLOGY. Formerly known as speech therapy, it includes the study and treatment of human communication—its development and disorders.

SPENT PHASE. A late development in PV leading to failure of the bone marrow and severe anemia.

SPERM. The reproductive cell of the male, which contains genetic information and participates in the act of fertilization of an ovum.

SPERM GRANULOMA. A collection of fluid that leaks from an improperly sealed or tied vas deferens. The fluid usually disappears on its own, but can be drained, if necessary.

SPERM OR SPERMATOZOA. The part of the semen that is generative—can cause fertilization of the female ovum.

SPERMATIC CORD. A tube-like structure that extends from the testicle to the groin area. It contains blood vessels, nerves, and a duct to carry spermatic fluid.

SPERMATOGENESIS. The process by which sperm develop to become mature sperm, capable of fertilizing an ovum.

SPERMICIDE. An agent that is destructive to sperm.

SPF. Sun protection factor; a number assigned to sunscreens that indicates the amount of UV-B radiation that is required to produce sunburn in the presence of the sunscreen, relative to the amount of UV-B radiation required to burn unprotected skin.

SPHINCTER. Ring of muscle between the bladder and the urethra that functions to close off the urethra.

SPIKE WAVE DISCHARGE. Characteristic abnormal wave pattern in the electroencephalogram that is a hallmark of an area that has the potential of generating a seizure.

SPILLOVER. In epidemiology, the sporadic transmission of a disease agent from a reservoir species to a non-reservoir species.

SPINA BIFIDA. A birth defect (a congenital malformation) in which there is a bony defect in the vertebral column so that part of the spinal cord, which is normally protected within the vertebral column, is exposed. People with spina bifida can suffer from bladder and bowel incontinence, cognitive (learning) problems, and limited mobility.

SPINAL CANAL. The cavity or hollow space within the spine that contains the spinal cord and the cerebrospinal fluid.

SPINAL CORD. Elongated nerve bundles that lie in the vertebral canal and from which the spinal nerves emerge.

SPINAL FUSION. An operation in which the bones of the lower spine are permanently joined together using a bone graft obtained usually from the hip.

SPINAL STENOSIS. A form of sciatica that is caused by a narrowing of the spinal canal in the lumbar vertebrae. The narrowing puts pressure on the roots of the sciatic nerve.

SPINE. A term for the backbone that includes the vertebrae, disks, and spinal cord as a whole.

SPIRAL CT. Also referred to as helical CT, this method allows for continuous 360-degree x-ray image capture.

SPIROCHETE. Any of a family of spiral- or coil-shaped bacteria known as Spirochetae.

SPIROMETER. A device that is used to test the air capacity of a person's lungs and the amount of air that enters and leaves the lungs during breathing.

SPIROMETRY. A test that measures breathing difficulty to determine asthma severity and response to treatment.

SPLEEN. An organ located at the left side of the stomach that acts as a reservoir for blood cells and produces lymphocytes and other products involved in fighting infection.

SPLENECTOMY. Surgical removal of the spleen.

SPLENOMEGALY. Enlargement of the spleen.

SPLINT. A thin piece of rigid material that is sometimes used during nasal surgery to hold certain structures in place until healing is underway.

SPONDYLITIS. An inflammation of the spine.

SPONDYLOARTHRITIS. A disease that causes inflammation of the joints between the spinal bones and the joints between the spine and the pelvis.

SPONDYLOSIS. Arthritis of the spine.

SPONTANEOUS PNEUMOTHORAX. Air in the chest cavity that occurs because of disease or other naturally occurring cause. Air and blood together in this space is called a pneumohemothorax.

SPORADIC. Isolated or appearing occasionally with no apparent pattern.

SPORE. A dormant form assumed by some bacteria, such as anthrax, that enable the bacterium to survive high temperatures, dryness, and lack of nourishment for long periods of time. Under proper conditions, the spore may revert to the actively multiplying form of the bacteria.

SPRUE. A disorder of impaired absorption of nutrients from the diet by the small intestine (malabsorption), resulting in malnutrition. Two forms of sprue exist: tropical sprue, which occurs mainly in tropical regions; and celiac sprue, which occurs more widely and is due to sensitivity to the wheat protein gluten.

SPUR. Any projection from a bone.

SPUTUM. Matter ejected from the lungs, bronchi, and trachea through the mouth.

SPUTUM CYTOLOGY. A lab test in which a microscope is used to check for cancer cells in the sputum.

SQUAMOUS CELL CANCER. A form of skin cancer that usually originates in sun-damaged areas or preexisting lesions; at first local and superficial, it may later spread to other areas of the body.

SQUAMOUS CELLS. Flat epithelial cells, which usually make up the outer layer of epithelial tissue, the layer farthest away from the surface the epithelium covers.

SQUAMOUS EPITHELIAL CELLS. Thin, flat cells found in layers or sheets covering surfaces such as skin and the linings of blood vessels and esophagus.

SQUAMOUS INTRAEPITHELIAL LESION (SIL). Abnormal growth of squamous cells on the surface of the cervix.

ST. VITUS' DANCE. Another name for Sydenham's chorea. St. Vitus was a fourth-century martyr who became the patron saint of dancers and actors during the Middle Ages. He was also invoked for protection against nervous disorders, epilepsy, and the disease that bears his name.

WWW.BOOKBAZ.IR

STABILIZATION. A set of procedures for preventing shock in an injured person by protecting the airway, controlling bleeding (if any), keeping the person warm, and preventing injury to the spinal cord.

STAGING. Classifying the extent or severity of a disease based on established criteria.

STAGING SYSTEM. A system based on how far the cancer has spread from its original site, developed to help the physician determine how best to treat the disease.

STAMINA. Staying power, endurance.

STANDARD DEVIATION. A measure of the distribution of scores around the average (mean). In a normal distribution, two standard deviations above and below the mean includes about 95% of all samples.

STANDARDIZATION. The process of determining established norms and procedures for a test to act as a standard reference point for future test results.

STAPHYLOCOCCAL INFECTION. An infection caused by the organism *Staphlococcus*. Infection by this agent is common and is often resistant to antibiotics.

STAPHYLOCOCCAL SCALDED SKIN SYNDROME. A disease caused by *Staphylococcus aureus*, in which large sheets of skin may peel away from the body. It most often affects infants, young children, and people with weakened immune systems.

STATIC ENCEPHALOPATHY. A disease of the brain that does not get better or worse.

STATINS. Lipid-lowering drugs that decrease LDL ("bad") cholesterol and moderately increase HDL ("good") cholesterol in the blood.

STATUS MIGRAINOSUS. The medical term for an acute migraine headache that lasts 72 hours or longer.

STEAM DISTILLATION. A process of extracting essential oils from plant products through a heating and evaporation process.

STEATORRHEA. An excessive amount of fat in the stool.

STEM CELL. A cell from which other cells form or develop.

STEM CELL TRANSPLANT. Treatment procedure by which young blood stem cells are collected from the patient (autologous) or another matched donor (allogeneic). High-dose chemotherapy and/or radiation is given, and the stem cells are reinserted into the patient to rebuild his or her immune system.

STENOSIS. A narrowing or constriction of the diameter of a passage or orifice, such as a blood vessel.

STENT. A device made of expandable, metal mesh that is placed (by using a balloon catheter) at the site of a narrowing artery; the stent stays in place to keep the artery open.

STEREOPSIS. The visual perception of depth, or the ability to see three-dimensionally. For this to occur, the person must be binocular.

STEREOTACTIC. Precise guidance or positioning.

STEREOTACTIC BIOPSY. A biopsy taken by precisely locating areas of abnormal growth through the use of delicate instruments.

STEREOTACTIC BRAIN NEEDLE BIOPSY. In this procedure a computer uses information from a CT or MRI to create a three-dimensional map of the operation site to better guide the needle to perform the biopsy.

STEREOTACTIC TECHNIQUE. A technique used by neurosurgeons to pinpoint locations within the brain. It employs computer imaging to create an external frame of reference.

STERILE. Free of microorganisms.

STERILITY. Inability to conceive a child.

STERNUM. The breastbone. The sternum is located over the heart, is the point of attachment for ribs at the front of the body and provides protection to the heart beneath it.

STEROID. A drug used to reduce swelling and fluid accumulation.

STEROLS. Steroid alcohols, such as cholesterol, that are widely distributed in the body.

STETHOSCOPE. A medical instrument for listening to a patient's heart and lungs.

STEVENS-JOHNSON SYNDROME. A severe inflammatory skin eruption that occurs as a result of an allergic reaction or respiratory infection.

STIGMA. Any personal attribute that causes a person to be socially shamed, avoided, or discredited. Mental disorders are a common cause of stigma.

STIMULANTS. A class of drugs, including Ritalin, used to treat people with autism. They may make children calmer and better able to concentrate, but they also may limit growth or have other side effects.

STIMULUS. A factor capable of eliciting a response.

STOCKINETTE. A soft elastic material used for bandages and clothing for infants.

STOMA. A surgical opening made in the abdominal wall to allow waste products to pass directly to the outside.

STOMATITIS. Inflammation of the lining of the mouth, gums, or tongue.

STONES. Also known as calculi, stones result from an excessive build-up of mineral crystals in the kidney. Symptoms of stones include intense pain in the lower back or abdomen, urinary tract infection, fever, burning sensation on urination, and/or blood in the urine.

STOOL. The solid waste that is left after food is digested. Stool forms in the intestines and passes out of the body through the anus.

STOOL DNA TESTING (SDNA). Stool sample testing that detects abnormal DNA from polyps or cancer.

STORE-AND-FORWARD TELEHEALTH. Telehealth in which images, video, or other patient data are captured and stored on a computer (or mobile device) and then transmitted (forwarded) at a later time to a specialist at another location for a diagnosis. Store-and-forward is also called "asynchronous telehealth."

STRABISMUS. A condition in which the eyes are misaligned and point in different directions. One eye may look straight ahead, while the other turns inward, outward, upward, or downward. This is also called crossed-eyes.

STRANGULATED HERNIA. A hernia that is so tightly incarcerated outside the abdominal wall that the intestine is blocked and the blood supply to that part of the intestine is cut off.

STRANGULATED OBSTRUCTION. An obstruction in which a loop of the intestine has its blood supply cut off.

STRANGULATION. A condition in which a vessel, section of the intestine, or other body part is compressed or constricted to the point that blood cannot circulate.

STRAWBERRY TONGUE. A sign of scarlet fever in which the tongue appears to have a red coating with large raised bumps.

STREET DRUG. A substance purchased from a drug dealer; may be a legal substance, sold illicitly (without a prescription, and not for medical use), or it may be a substance that is illegal to possess.

STREP THROAT. A sore throat caused by infection with *Streptococcus* bacteria. Symptoms include sore throat, chills, fever, and swollen lymph nodes in the neck.

STREPTOCOCCAL. Pertaining to any of the *Streptococcus* bacteria. These organisms can cause pneumonia, skin infections, and many other diseases.

STREPTOCOCCAL INFECTION. An infection caused by a pathogenic bacterium of one of several species of the genus *Streptococcus* or their toxins. Almost any organ in the body may be involved.

STREPTOCOCCUS. A gram-positive, round or oval bacteria in the genus *Streptococcus*. Group A streptococci cause a number of human diseases including strep throat, impetigo, and ASPGN.

STRESS FRACTURE. A hairline fracture (narrow crack along the surface of a bone) that is caused by repeated stress to the bone, such as from jogging, rather than from a single heavy blow.

STRESS HARDINESS. A personality characteristic that enables persons to stay healthy in stressful circumstances. It includes belief in one's ability to influence the situation; being committed to or fully engaged in one's activities; and having a positive view of change.

STRESS INCONTINENCE. Leakage of urine upon movements that put pressure on the abdominal muscles such as coughing, sneezing, laughing, or exercise. One of four types of incontinence.

STRESS MANAGEMENT. A set of techniques and programs intended to help people deal more effectively with stress in their lives by analyzing the specific stressors and taking positive actions to minimize their effects. Most stress management programs deal with job stress and workplace issues.

STRESS TEST. A test used to determine how the heart responds to stress. It usually involves walking on a treadmill or riding a stationary bike at increasing levels of difficulty, while the electrocardiogram, heart rate and blood pressure are monitored. If the patient is unable to walk on a treadmill or ride a stationary bike, medications may be used to produce similar results.

STRESSOR. A stimulus or event that provokes a stress response in an organism. Stressors can be categorized as acute or chronic, and as external or internal to the organism.

STRIATED MUSCLE. Also known as striped muscle; it includes muscles of the skeletal system and of the heart.

WWW.BOOKBAZ.IR

STRICTURE. An abnormal narrowing of a duct or canal.

STRIDOR. A harsh or crowing breath sound caused by partial blockage of the patient's upper airway.

STRING TEST. A test performed to diagnose threadworm infection. The patient is asked to swallow a weighted string that absorbs stomach juices, which can be analyzed for the presence of threadworm larvae.

STROKE. Irreversible damage to the brain caused by insufficient blood flow to the brain as the result of a blocked artery. Damage can include loss of speech or vision, paralysis, cognitive impairment, and death.

STROMA. A term used to describe the supportive tissue surrounding a particular structure. An example is that tissue which surrounds and supports the actually functional lung tissue.

STROMAL. A term used to describe the supportive tissue surrounding a particular structure. An example is that tissue which surrounds and supports the actually functional lung tissue.

STRUCTURAL INTEGRATION. The term used to describe the method and philosophy of life associated with Rolfing. Its fundamental concept is the vertical line.

STUNTING. A height more than two standard deviations from the median height for the age in the reference population.

STYPTIC. Any remedy with an astringent and hemostatic (stopping bleeding) quality.

SUBACUTE. An abnormal condition present in a person who appears to be clinically well.

SUBARACHNOID HEMORRHAGE (SAH). Loss of blood into the subarachnoid space, the fluid-filled area that surrounds the brain tissue.

SUBARACHNOID SPACE. The space underneath the arachnoid membrane, a thin membrane enclosing the brain and spinal cord.

SUBCLAVIAN. Located beneath the collarbone (clavicle).

SUBCORTICAL APHASIA. A condition characterized by either partial or total loss of the ability to communicate verbally or using written words as a result of damage to non-language-dominated areas of the brain. This condition may be caused by a stroke, head injury, brain tumor, or infection.

SUBCUTANEOUS. The area directly beneath the skin.

SUBCUTANEOUS EMPHYSEMA. A pathologic accumulation of air underneath the skin resulting from improper insufflation technique.

SUBCUTIS. The deepest layer of skin tissue that lies below the dermis.

SUBDURAL HEMATOMA. A collection of blood or a clot trapped under the dura mater, the outermost membrane surrounding the brain and spinal cord, often causing neurological damage due to pressure on the brain.

SUBJECTIVE. Influenced by the perspective of the information provider; potentially biased.

SUBLUXATION. Misalignment between vertebrae that structurally and functionally impairs nerve function.

SUBSTANCE ABUSE DISORDER. Disorder that is characterized by an individual's need for more of a drug or alcohol than intended, an inability to stop using by choice, and an ongoing difficulty in recovering from the effects of the substance.

SUBSTANTIA NIGRA. One of the movement control centers of the brain.

SUBTHRESHOLD. A term used in psychiatry to describe a condition that has significant clinical features but does not meet the full criteria of major disorders. Adjustment disorders are considered subthreshold disorders.

SUCCIMER (CHEMET). A drug used to remove excess lead from the body.

SUCCUSSION. The act of shaking diluted homeopathic remedies as part of the process of potentization.

SUCROSE. Table sugar; a disaccharide consisting of glucose and fructose.

SUDDEN UNEXPECTED DEATH SYNDROME (SUD). Sometimes called sudden unexpected nocturnal death syndrome; the abrupt, unforeseen death of an adolescent or adult, often during sleep.

SUGARS. Carbohydrates having the general composition of one part carbon, two parts hydrogen, and one part oxygen.

SUICIDE GESTURE. Attempted suicide by a low-lethality method, with a low level of intent or planning and only minor physical damage; sometimes called pseudocide.

SUICIDE MAGNET. A bridge, tall building, or geographic location that acquires a reputation for suicides and suicide attempts.

SULFADOXONE/PYRIMETHAMINE (FANSIDAR). An antimalarial drug developed in the 1960s. It is the first drug tried in some parts of the world where chloroquine resistance is widespread. It has been associated with severe allergic reactions due to its sulfa component.

SULFINPYRAZONE. A drug that corrects hyperuricemia by increasing the urinary excretion of urate.

SULFITE. A type of preservative that causes allergic reactions in some people.

SULFONAMIDE. A sulfa drug, one of a large group of drugs used to treat bacterial infections.

SULFONAMIDE DRUGS. A group of antibacterial drugs used to treat infections of the lungs and skin, among other things.

SUMMARY OF BENEFITS AND COVERAGE (SBC). A standard form that health insurance companies and plans must use under the PPACA to explain their plans and allow for easy comparisons of plans.

SUNBLOCK. A skin preparation containing an active ingredient, such as titanium oxide, that prevents sunburn by physically blocking out ultraviolet radiation.

SUNSCREEN. Products which block the damaging rays of the sun. Good sunscreens contain either para-aminobenzoic acid (PABA) or benzophenone, or both. Sunscreen protection factors range from 2–45.

SUNSETTING. Confusion or agitation in the evening.

SUPERINFECTION. Infection by a second virus after a previous infection by a different virus has become well established.

SUPERIOR VENA CAVA. The major vein that carries blood from the upper body to the heart.

SUPERIOR VENA CAVA (SVC) SYNDROME. A condition seen in lung cancer patients where the tumor presses against a large blood vessel and causes various symptoms.

SUPPORT GROUP. A group whose primary purpose is the provision of empathy and emotional support for its members. Support groups are less formal and less goal-directed than group therapy.

SUPPORTIVE THERAPY. An approach in psychotherapy that seeks to encourage or emotionally support the patient, as distinct from insight-oriented or educational approaches to treatment.

SUPPOSITORY. A solid medication that slowly dissolves after being inserted into the rectum or other body cavity.

SUPPURATE. To produce or discharge pus.

SUPRAGLOTTITIS. Another term for epiglottitis.

SUPRASPINATUS. A muscle at the top of the shoulder blade.

SUPRAVENTRICULAR. A term for an event that occurs in the upper chambers (atria) of the heart.

SUPRAVENTRICULAR TACHYCARDIA. A fast heartbeat that originates above the ventricles.

SURFACE TENSION. The attraction of molecules in a fluid for each other.

SURFACTANT. A substance secreted by the alveoli in the lungs that reduces the surface tension of lung fluids, allowing gas exchange and helping maintain the elasticity of lung tissue.

SURGICAL SITE INFECTION (SSI). An infection that originates at the site in the body that was operated upon.

SURVEILLANCE. In epidemiology, the monitoring and reporting of cases of contagious disease in order to establish patterns of its spread to prevent or minimize the development of epidemics and pandemics.

SURVIVOR'S GUILT. A mental condition in which a person feels that he or she did something wrong by surviving a disaster in which others died. It can also affect therapists and first responders who feel that they did not do enough to rescue or help people caught in a disaster.

SURVIVORSHIP CARE PLAN (SCP). The record of a patient's cancer history and recommendations for follow-up care. It details the responsibilities of all care providers, whether cancer-related, primary care, or psychosocial. The SCP is intended to improve the survivor's care coordination and avoid duplication of resources.

SUTURES. Materials used in closing a surgical or traumatic wound.

SWEAT GLANDS. Tiny glands scattered throughout the skin that produce sweat.

SWIMMER'S ITCH. An allergic skin inflammation caused by a sensitivity to flatworms that die under the skin, causing an itchy rash.

SYDENHAM'S CHOREA. A serious manifestation of acute rheumatic fever that commonly occurs in children ages seven through 14, peaking at age eight. This disease of the central nervous system is characterized by emotional instability, purposeless movements, and muscular weakness.

WWW.BOOKBAZ.IR

SYLVATIC. Pertaining to or living in the woods or forested areas. The form of yellow fever transmitted by mosquitoes to rainforest monkeys is called sylvatic yellow fever.

SYMBIOSIS. A close, long-term relationship between individuals of two difference species.

SYMPATHETIC NERVE. A nerve of the autonomic nervous system that regulates involuntary and automatic reactions, especially to stress.

SYMPATHETIC NERVOUS SYSTEM. The "fight or flight" division of the autonomic nervous system that increases heart rate, blood pressure, and respiratory rate, among other functions, in active or stressful situations.

SYMPATHOMIMETIC. Denoting a drug that mimics the effects of stimulation of organs and structures by the sympathetic nervous system. The sympathetic nervous system pertains to the part of the nervous system originating in the thoracic and lumbar regions of the spinal cord. In general, it inhibits or opposes the physiological effects of another aspect of the nervous system, as in tending to reduce digestive secretions, speed up the heart, and contract the blood vessels.

SYMPTOMATIC. Refers to treatment that addresses the symptoms of an illness, but not its underlying cause.

SYNAPSE. A connection between nerve cells, by which nervous excitation is transferred from one cell to the other.

SYNCHRONIZED ELECTRICAL CARDIOVERSION. The term used to describe cardioversion by the application of a controlled electric shock to the patient's chest.

SYNCOPE. A loss of consciousness over a short period of time, caused by a temporary lack of oxygen in the brain.

SYNDACTYLY. A fusion of two or more toes or fingers.

SYNDEMIC. A combination of two or more diseases in a given population in which there is a positive biological interaction between the two diseases that intensifies their negative effects on health.

SYNDROME. A group of signs or symptoms that occur together and characterize or define a particular disease or disorder.

SYNDROME OF INAPPROPRIATE ANTIDIURETIC HORMONE (SIADH). A potentially fatal condition of excessive secretion of ADH, leading to concentrated urine and blood sodium deficiency.

SYNDROME X. A term that was sometimes used for metabolic syndrome when the syndrome was first identified in the 1960s.

SYNERGISTIC. The combined action of two or more processes is greater than the sum of each acting separately.

SYNOVIAL FLUID. A fluid that lubricates the joints, facilitates motion, and helps prevent wearing of the bones.

SYNOVIAL JOINT. A particular type of joint that allows for movement in the articular bones.

SYNOVIAL MEMBRANE. The membrane that lines the inside of the articular capsule of a joint and produces lubricating synovial fluid.

SYNOVIAL TENDON SHEATH. Where the tendons cross joints, they are sheathed in thin membranes known as synovium, which provide lubrication to decrease friction.

SYNOVITIS. Inflammation of the synovium, the thin membrane in the joint.

SYNTHETIC. Made with an artificial chemical process, often to resemble a natural product.

SYPHILIS. This disease occurs in two forms. One is a sexually transmitted disease caused by a bacteria. The second form is not sexually transmitted, but passed on by direct contact with the patient or through use of shared food dishes and utensils.

SYSTEMIC. Affecting the entire body.

SYSTEMIC CIRCULATION. Blood vessels not involved in carrying blood to and from the lungs between the right and left sides of the heart.

SYSTEMIC LUPUS ERYTHEMATOSUS (SLE). A chronic inflammatory disease in which inappropriate immune system reactions cause abnormalities in the blood vessels and connective tissue.

SYSTEMIC SCLEROSIS. A rare disorder that causes thickening and scarring of multiple organ systems.

SYSTOLE. Period while the heart is contracting.

SYSTOLIC. Referring to the rhythmic contraction of the heart (systole) as the blood in the chambers is forced out. Systolic blood pressure is blood pressure measured during the systolic phase.

SYSTOLIC BLOOD PRESSURE. The point at which arterial pressure is highest (when the ventricles are contracting). The first measurement in a blood pressure reading.

T

T CELL. T lymphocytes; immune-system white blood cells that help coordinate immune responses.

TABES DORSALIS. A progressive deterioration of the spinal cord and spinal nerves that is associated with tertiary syphilis.

TABLEWORK. The passive phase of Trager therapy, in which the practitioner uses gentle and noninvasive movements to allow the client to relax deeply and experience physical movement as free and effortless.

TAC. A topical anesthetic mixture containing tetracaine, epinephrine (adrenaline), and cocaine.

TACHYCARDIA. A rapid heartbeat, usually over 100 beats per minute.

TACTILE. The perception of touch.

TAENIASIS. Parasitic infection caused by the presence of tapeworms from the *Taenia* genus, such as the pork tapeworm (*Taenia solium*) or the beef tapeworm (*Taenia saginata*).

TALK THERAPY. A general term for any form of psychotherapy based on conversational interaction between a trained therapist and a client. It includes psychodynamic therapy, humanistic therapy, and the various behavioral therapies as well as psychoanalysis.

TAMOXIFEN. A drug that blocks the activity of estrogen; used to prevent or treat breast cancer.

TAMPONADE. To occlude by pressure.

TANNER STAGES. A set of scales to measure sexual development during puberty; named for James Tanner (1920–2010), the British pediatrician who devised it.

TAPERING. Gradually reducing the amount of a drug if stopping it abruptly would cause unpleasant withdrawal symptoms.

TAPEWORM. An intestinal parasite that attaches to the intestine or travels to other organs such as the liver and lungs.

TARDIVE DYSKINESIA. Involuntary movements of the face and/or body that are a side effect of the long-term use of some older antipsychotic (neuroleptic) drugs. Tardive dyskinesia affects 15–20% of patients on long-term neuroleptic treatment.

TARGET HEART RATE. The heart rate, in beats per minute (bpm), that should be maintained during cardiovascular exercise by an individual of a given age.

TARGETED DRUG. A drug that interferes with specific molecules involved in cancer cell growth and/or survival; often chosen on the basis of a cancer marker.

TARGETED THERAPY. In cancer treatment, a type of drug therapy that blocks tumors by interfering with specific molecules that the cancer cells need for growth. Also called biologic therapy, targeted therapy is less harmful to normal cells than traditional chemotherapy.

TARTAR. A hardened yellow or brown mineral deposit from unremoved plaque; also called calculus.

TASER. Also called a conducted electrical weapon or CEW, a taser is an electroshock device used by some police departments in various countries to subdue armed or otherwise dangerous suspects without having to use lethal force. Tasers work by interfering with the capacity to control voluntary muscles. The name *taser* is an acronym for *Thomas A. Swift's Electric Rifle*, an adventure novel about a fictional weapon published in 1911.

TAU PROTEIN. A protein involved in maintaining the internal structure of nerve cells. Tau protein is damaged in AD and forms neurofibrillary tangles.

TAURINE. An amino acid that is important in the development of brain tissue. Taurine is a key component of bile which is needed to digest fats.

TAY-SACHS DISEASE. An inherited disease prevalent among the Ashkenazi Jewish population of the United States. Infants with the disease are unable to process a certain type of fat that accumulates in nerve and brain cells, causing mental and physical disabilities and death by age four.

TDAP. A full-strength tetanus and reduced-strength diphtheria and acellular pertussis combination vaccine.

TEAR. A drop of the clear, salty fluid secreted by the lachrimal gland.

TECHNETIUM. A radioactive isotope frequently used in radionuclide scanning of the heart and other organs. It is produced during nuclear fission reactions.

TELANGIECTASES. Spidery red skin lesions caused by dilated blood vessels.

TELANGIECTASIA. Small blood veins visible at the surface of the skin of the nose and cheeks.

TELEMEDICINE. The use of electronic communication and information technologies to provide or support clinical care at a distance. It may include case management and psychological counseling.

WWW.BOOKBAZ.IR

TELEMENTAL HEALTH. The practice of psychiatry or psychotherapy via videoconferencing or similar communications technology.

TELEMENTORING. The use of audio, video, and other telecommunications and electronic information processing technologies to provide individual guidance or direction among health care professionals.

TELEMONITORING. The use of communications technologies and electronic information processing to monitor the vital signs or general health status of a patient from a distance.

TEMPERAMENT. A person's natural or genetically determined disposition.

TEMPORAL ARTERITIS. Also known as giant cell arteritis. Inflammation of the large arteries located in the temples which is marked by the presence of giant cells and symptoms of headache and facial pain.

TEMPORAL BONES. The compound bones that form the left and right sides of the skull.

TEMPORAL LOBE. The part of each side or hemisphere of the brain that is on the side of the head, nearest the ears.

TEMPOROMANDIBULAR JOINT (TMJ). The jaw joint formed by the mandible (lower jaw bone) moving against the temporal (temple and side) bone of the skull.

TEMPOROMANDIBULAR JOINT SYNDROME (TMJ SYNDROME). Pain and other symptoms affecting the head, jaw, and face that are caused when the jaw joints and muscles controlling them don't work together correctly.

TENDINITIS. Inflammation of a tendon, which is a tough band of tissue that connects muscle to bone.

TENDON. A strong connective tissue that connects muscle to bone.

TENDON REFLEX. A reflex action, such as a knee jerk, in which a light blow to the tendon causes the muscle to contract.

TENDON SHEATH. A membrane covering a tendon.

TENESMUS. Straining to urinate or defecate without being able to do so. Tenesmus is a characteristic feature of bacillary dysentery.

TENOSYNOVITIS. Inflammation of a tendon and its enveloping sheath.

TENOTOMY. A surgical procedure that cuts the tendon of a contracted muscle to allow lengthening.

TENS. The abbreviation for transcutaneous electrical nerve stimulation, a technique used to control chronic pain. Electrodes placed over the painful area deliver a mild electrical impulse to nearby nerve pathways, thereby easing pain.

TENSILON TEST. A test for diagnosing myasthenia gravis. Tensilon is injected into a vein and, if the person has MG, their muscle strength will improve for about five minutes.

TENSION-TYPE HEADACHE. A dull pain that seems to exert pressure on the head; the most common form of headache.

TERATOGEN. Any drug, chemical, maternal disease, or exposure that can cause physical or functional defects in an exposed embryo or fetus.

TESTES. The male sex organs that make sperm and male hormones.

TESTICLES. The testes along with their enclosing structures.

TESTICULAR CANCER. A cancer that originates in the testes.

TESTICULAR TORSION. Twisting of the testicle around the spermatic cord, cutting off the blood supply to the testicle. It is considered a urologic emergency.

TESTOSTERONE. A male steroid hormone produced in the testes and responsible for the development of secondary sex characteristics.

TESTOSTERONE REPLACEMENT THERAPY (TRT). Treatment for low testosterone levels.

TETANUS. Lockjaw; a rare but often fatal infection caused by the bacterium *Clostridium tetani* that lives in soil, dust, and manure.

TETANUS TOXOID. Tetanus toxoid is a vaccine used to prevent tetanus (also known as lockjaw).

TETANY. A disorder of the nervous system characterized by muscle cramps, spasms of the arms and legs, and numbness of the extremities.

TETRALOGY OF FALLOT. A defect in which the blood pumped through the body has too little oxygen. Tetralogy of Fallot includes four defects: a ventricular septal defect, narrowing at or beneath the pulmonary valve, infundibular pulmonary stenosis (obstruction of blood flow from the right ventricle through the pulmonary valve), and overriding aorta (the aorta crosses the ventricular septal defect into the right ventricle).

TEXTURED VEGETABLE PROTEIN (TVP). A meat substitute made from defatted soybean flour formed into a dough and cooked by steam while being forced through an extruder. It resembles ground beef in texture and can replace it in most recipes. TVP is also known as textured soy protein or TSP.

TH CELLS. T-helper cells; TH1 cells fight bacteria and viruses and protect against allergies; TH2 cells fight parasitic infections and promote the production of excessive IgE.

THALAMOTOMY. A surgical procedure that destroys part of a large oval area of gray matter within the brain that acts as a relay center for nerve impulses. The thalamus is an essential part of the nerve pathway that controls intentional movement. By destroying tissue at a particular spot on the thalamus, the surgeon can interrupt the nerve signals that cause tremor.

THALAMUS. A large oval area of gray matter within the brain that relays nerve impulses from the basal ganglia to the cerebellum, both parts of the brain that control and regulate muscle movement.

THALASSEMIA. A group of inherited disorders that affects hemoglobin production. Because hemoglobin production is impaired, a person with this disorder may suffer mild to severe anemia. Certain types of thalassemia can be fatal.

THANATOLOGY. The medical, psychological, or legal study of death and dying.

THELARCHE. The onset of breast development in girls. It is usually first noticed as a firm but tender lump directly under the center of the nipple.

T-HELPER CELLS. A cellular component of the immune system that plays a major role in ridding the body of bacteria and viruses, characterized by the presence of the CD4 protein on its surface; the type of cell that divides uncontrollable with CTCL.

THERAPEUTIC. Curative or healing.

THERAPEUTIC WRITING. A treatment technique in which patients are asked to write an account of the traumatic event and their emotional responses to it.

THIAMINE. A B vitamin essential for the body to process carbohydrates and fats. Alcoholics may suffer complications (including Wernike-Korsakoff syndrome) from a deficiency of this vitamin.

THIAMINE PYROPHOSPHATE (TPP). The coenzyme containing thiamine that is essential in converting glucose to energy.

THIAZIDE DIURETIC. A particular class of medication that encourages urine production.

THIMEROSAL. A crystalline organic mercury compound used as an antifungal and antibacterial agent and present in very small amounts in some vaccines.

THIRD SPACE. The interstitial space.

THORACENTESIS. A procedure in which fluid is withdrawn from the pleural cavity through a needle inserted between the ribs. The fluid may be withdrawn either for diagnostic tests or to drain the cavity.

THORACIC. Relating to the chest.

THORACIC ANEURYSM. Aneurysm that involves the ascending, arch, or descending thoracic aorta.

THORACIC AORTIC ANEURYSM. Occurs when an area in the thoracic section of the aorta (the chest) is weakened and bulges like a balloon. The thoracic section supplies blood to the upper body.

THORACIC VERTEBRAE. The vertebrae in the chest region to which the ribs attach.

THORACOSCOPY. Examination of the contents of the chest through a thin, lighted tube passed through a small incision.

THORACOTOMY. Open chest surgery.

THORAX. The chest area, which runs between the abdomen and neck and is encased in the ribs.

THREADWORM. Any long, thin nematode worm.

THROAT CULTURE. A test for strep throat that involves swabbing the back of the throat and sending the swab to a laboratory, which determines whether bacteria are present.

THROMBIN. An enzyme in blood plasma that catalyzes the conversion of fibrinogen to fibrin during the last stage of the clotting process.

THROMBIN INHIBITOR. Thrombin inhibitors are one type of anticoagulant medication, used to help prevent formation of harmful blood clots in the body by blocking the activity of thrombin.

THROMBOCYTE. Another name for platelet.

THROMBOCYTOPENIA. An abnormal decline in the number of platelets in the blood.

THROMBOCYTOSIS. A vascular condition characterized by high blood platelet counts.

THROMBOEMBOLISM. A blood clot that can break free and block a blood vessel elsewhere in the body.

WWW.BOOKBAZ.IR

THROMBOLYSIS. A treatment that opens up blood flow and may prevent permanent damage to the blood vessels.

THROMBOLYTIC. Clot-buster; a medication that dissolves blood clots.

THROMBOLYTICS. Drugs that dissolve blood clots. Thrombolytics are used to treat embolisms.

THROMBOPHLEBITIS. Inflammation of the veins, usually in the legs, which causes swelling and tenderness in the affected area.

THROMBOPLASTIN. A enzyme in blood that converts prothrombin to thrombin.

THROMBOSIS. Formation of a clot in the blood that either blocks, or partially blocks a blood vessel. The thrombus may lead to infarction, or death of tissue, due to a blocked blood supply.

THROMBOTIC. Relating to, caused by, or characterized by thrombosis.

THROMBOTIC STROKE. Cerebral thrombosis; a type of ischemic stroke caused by a blood clot formed within a blood vessel in the brain.

THRUSH. An opportunistic infection with the fungus *Candida albicans* that causes white patches in the oral cavity.

THYMOMA. A tumor that originates in the thymus, a small gland just in front of the heart that produces hormones necessary for the development of certain components of the immune system.

THYMUS. A gland located in the front of the neck that coordinates the development of the immune system.

THYROID. A gland in the neck overlying the windpipe that regulates the speed of metabolic processes by producing a hormone, thyroxin.

THYROID STIMULATING HORMONE (THYROTROPIN). A hormone that stimulates the thyroid gland to produce hormones that regulate metabolism.

THYROID STORM. A rare but potentially life-threatening complication of hyperthyroidism, characterized by fever over 104°F, irregular heart rhythm, vomiting, diarrhea, dehydration, coma, and death.

THYROIDECTOMY. Surgical removal of the thyroid gland.

THYROIDITIS. Inflammation of the thyroid gland. It can be caused by a viral infection, a malfunction of the immune system, or certain medications.

THYROTOXICOSIS. A condition resulting from high levels of thyroid hormones in the blood.

THYROXIN. The hormone secreted by the thyroid gland.

THYROXINE (T_4). The thyroid hormone that regulates many essential body processes.

TIBIA. The larger of two leg bones that lie beneath the knee. The tibia is sometimes called the shin bone.

TIC. A sudden involuntary behavior that is difficult or impossible for the person to suppress. Tics may be either motor (related to movement) or vocal, and may become more pronounced under stress.

TICK-BORNE DISEASE. A disease that is spread to animals by the bite of an infected tick.

TILT TABLE. Also called a tiltboard, an apparatus for rotating a person from horizontal to an oblique or vertical position.

TINEA. A superficial infection of the skin, hair, or nails, caused by a fungus and commonly known as ringworm.

TINNITUS. A ringing sound or other noise in the ear.

TISSUE PLASMINOGEN ACTIVATOR (TPA). A drug that can dissolve a blot clot in the brain and halt an ongoing ischemic stroke.

TISSUE-FLAP SURGERY. Breast reconstruction using tissues from elsewhere in the body.

TITER. A dilution of a substance with an exact known amount of fluid. For example, one part of serum diluted with four parts of saline is a titer of 1:4.

TITRATE. To analyze the best end point (for dose) for a medication.

TNM SYSTEM. A commonly used staging system that examines the main tumor (T), the lymph nodes (N), and metastases (M).

TOCOLYTIC. A medication that inhibits uterine contractions.

TOFU. Bean curd; a soft food made by coagulating soymilk with an enzyme, calcium sulfate, or an organic acid, and pressing the resulting curds into blocks or chunks. Tofu is frequently used in vegetarian dishes as a meat or cheese substitute.

TOLERABLE UPPER INTAKE LEVEL (UL). The highest daily intake level of a nutrient that is unlikely to cause adverse health effects in almost all individuals in the general population, as determined by the U.S. Institute of Medicine.

TOLERANCE. A decrease in sensitivity to a drug. When tolerance occurs, a person must take more and more of the drug to get the same effect.

TOMOGRAPHY. A technique for producing a focused image of the structures at a specific depth within the body, while blurring details at other depths.

TONIFICATION. Acupuncture technique for strengthening the body.

TONOMETER. An instrument that measures intraocular pressure (IOP).

TONOMETRY. The measurement of pressure.

TONSILLECTOMY. Surgical removal of the tonsils.

TONSILLITIS. Inflammation of a tonsil, a small mass of tissue in the throat.

TONSILS. Common name for the palatine tonsils, which are lymph masses in the back of the mouth, on either side of the tongue.

TOPHUS (PLURAL, TOPHI). A chalky deposit of a uric acid compound found in gout. Tophi occur most frequently around joints and in the external ear.

TOPICAL. Not ingested; applied to the outside of the body, for example to the skin, eye, or mouth.

TOPICAL CORTICOSTEROIDS. Cortisone and related drugs used on the skin and in the eye, usually for allergic conditions.

TORSION. The action of twisting.

TORTUOUS ARTERIES. Arteries with many bends and twists.

TOTAL GASTRECTOMY. Surgical removal (excision) of the entire stomach.

TOTAL LUNG CAPACITY. The volume of air in the lungs at the end of a deep breath. The normal value in adults is between 4 and 6 quarts.

TOTAL LUNG CAPACITY TEST. A test that measures the amount of air in the lungs after a person has breathed in as much as possible.

TOTAL MASTECTOMY. Simple mastectomy; removal of only the breast tissue, nipple and a small portion of the overlying skin.

TOTAL PARENTERAL NUTRITION (TPN). A solution containing all the required nutrients, including protein, fat, calories, vitamins, and minerals, which is injected over the course of several hours, into a vein. TPN provides a complete and balanced source of nutrients for patients who cannot consume a normal diet.

TOTAL-SKIN ELECTRON BEAM THERAPY. A method of radiation therapy used to treat CTCL that involves bombarding the entire body surface with high-energy electrons.

TOURETTE SYNDROME. A neurological disorder characterized by compulsive or vocal tics.

TOURNIQUET. A tube or pressure cuff that is tightened around a limb in order to compress a vein to stop bleeding.

TOURNIQUET. A tube or pressure cuff that is tightened around a limb in order to compress a vein to stop bleeding.

TOXEMIA. Poisoning of the blood.

TOXIC. Poisonous.

TOXIC MEGACOLON. Acute enlargement or dilation of the large intestine.

TOXIC SHOCK SYNDROME. An uncommon, but potentially fatal, disease that has been associated with the use of diaphragms and vaginal tampons. The symptoms include high fever, vomiting, and diarrhea.

TOXIC THYROID ADENOMA. Self-contained concentrations of thyroid tissue that may produce excessive amounts of thyroid hormone.

TOXICOLOGY. The branch of medicine that deals with the effects, detection, and treatment of poisons.

TOXIN. A poisonous substance produced by a microorganism, plant, or animal.

TOXOID. A preparation made from inactivated exotoxin, used in immunization.

TOXOPLASMA GONDII. A very common parasite that can cause toxoplasmosis and is a leading cause of death from food poisoning; although it infects large numbers of people, *T. gondii* is usually dangerous only in immunocompromised patients and in newly infected pregnant women.

TOXOPLASMOSIS. Disease caused by the parasite *Toxoplasma gondii* that can cause severe damage if vertically transmitted.

TRABECULAR MESHWORK. A sponge-like tissue located near the cornea and iris that functions to drain the aqueous humor from the eye into the blood.

WWW.BOOKBAZ.IR

TRABECULOPLASTY. Laser surgery that creates perforations in the trabeculum, to drain built up aqueous humor and relieve pressure.

TRABECULUM. Tissue that is a drainage point for aqueous humor in the eye.

TRACE ELEMENTS. A group of elements that are present in the human body in very small amounts but are nonetheless important to good health. They include chromium, copper, cobalt, iodine, iron, selenium, and zinc. Trace elements are also called micronutrients.

TRACER. A substance containing a radioisotope, injected into the body and followed in order to obtain information about various metabolic processes in the body.

TRACHEA. The windpipe. A tube extending from below the voice box into the chest where it splits into two branches, the bronchi, that go to each lung.

TRACHEOBRONCHIAL. Pertaining both to the tracheal and bronchial tubes or to their junction.

TRACHEOSTOMY. An opening through the neck into the trachea through which a tube may be inserted to maintain an effective airway and help a patient breathe.

TRACHEOSTOMY TUBE. A tube which is inserted into an incision in the trachea (tracheostomy) to relieve upper airway obstruction.

TRACHEOTOMY. A surgical procedure in which a hole is cut through the neck to open a direct airway through an incision in the trachea (windpipe).

TRACTION. The process of placing a bone, limb, or group of muscles under tension by applying weights and pulleys. The goal is to realign or immobilize the part or to relieve pressure on that particular area to promote healing and restore function.

TRADITIONAL CHINESE MEDICINE (TCM). The medical system of mainland China that is thousands of years old. When used as a complete system, it combines herbal medicines, dietary treatments, massage, acupuncture, and physical exercise (qigong and tai chi).

TRANQUILIZER. Medicine that has a calming effect and is used to treat anxiety and mental tension.

TRANS FAT. Fat that is produced by hydrogenation during food processing; trans fats increase bad cholesterol and decrease good cholesterol.

TRANSABDOMINAL ULTRASOUND. A small handheld instrument called a transducer is passed back and forth over the pelvic area to provide images of the abdomen.

TRANSCENDENTAL MEDITATION (TM). A meditation technique based on Hindu practices that involves the repetition of a mantra.

TRANSCORTICAL APHASIA. A condition characterized by either partial or total loss of the ability to communicate verbally or using written words that does not affect an individual's ability to repeat words, phrases, and sentences.

TRANSCRANIAL DIRECT CURRENT STIMULATION (TDCS). The passage of very low-level electrical current through specific areas of the brain to improve cognitive or motor function or treat mental disorders.

TRANSCRANIAL MAGNETIC STIMULATOR (TMS). A device for treating migraine headaches by stimulating the brain with magnetic energy.

TRANSCUTANEOUS ELECTRICAL NERVE STIMULATION (TENS). A migraine treatment in which a mild electrical current is passed through electrodes on the skin to stimulate nerves and block pain signals.

TRANSDUCER. The instrument that sends sound waves into organs of the body in order to produce ultrasound images.

TRANSESOPHAGEAL ECHOCARDIOGRAM (TEE). An invasive imaging procedure used to create a picture of the heart's movement, valves, and chambers. The test uses high-frequency sound waves that come from a small transducer passed down the patient's throat. TEE may be used in combination with Doppler ultrasound to evaluate the blood flow across the heart's valves.

TRANSFERENCE. The redirection of feelings and thoughts from early childhood experiences toward a person in the present, usually the analyst.

TRANSFERRIN. A protein in blood plasma that carries iron derived from food intake to the liver, spleen, and bone marrow.

TRANSFUSION. The transfer of blood from one person to another. Transfusions can be direct, in which blood is transferred from the donor to the recipient; or indirect, in which the blood is taken from the donor, stored in a container, and then given to the recipient.

TRANSGENIC ANIMAL. Animals that have had genes from other species inserted into their genetic code.

TRANSIENT ISCHEMIC ATTACK (TIA). Also known as a mini-stroke, a transient ischemic attack is caused by a temporary interruption of blood flow in an area of the brain. Unlike in a true stroke, normal brain function will return with 24 hours.

TRANSILLUMINATION. A technique by which a strong light is shone through body tissues to examine an organ or structure.

TRANSLOCATION. The transfer of one part of a chromosome to another chromosome during cell division. A balanced translocation occurs when pieces from two different chromosomes exchange places without loss or gain of any chromosome material. An unbalanced translocation involves the unequal loss or gain of genetic information between two chromosomes.

TRANSPLANTATION. Surgically cutting out hair follicles and replanting them in a different spot on the head.

TRANSPOSITION OF THE GREAT VESSELS. A cyanotic defect in which the blood pumped through the body has too little oxygen because the pulmonary artery receives its blood incorrectly from the left ventricle and the aorta incorrectly receives blood flow from the right ventricle.

TRANSSEXUAL. Person desiring to acquire the external appearance of a member of the opposite gender.

TRANSTRACHEAL BIOPSY. A transtracheal biopsy is the removal of a small piece of tissue from across the trachea or windpipe for examination under a microscope.

TRANSUDATE. The type of pleural effusion seen with heart failure or other disorders of the circulation. It features clear fluid containing few cells and little protein.

TRANSUDATION. The passage of fluid, as through blood vessels into the vagina.

TRANSURETHRAL RESECTION OF THE PROSTATE (TURP). Surgical removal of a portion of the prostate through the urethra, a method of treating the symptoms of an enlarged prostate, whether from BPH or cancer.

TRANSVERSE PRESENTATION. A baby laying sideways across the cervix rather than head first.

TRANSVESTIC FETISHISM. A condition in which a person is sexually aroused by wearing the clothing of the other sex (as distinct from cross-dressing for a theater role or costume party).

TRAUMA. A disastrous or life-threatening event that can cause severe emotional distress and/or severe physical injury.

TRAUMATIC BRAIN INJURY (TBI). Damage to the brain from sudden trauma.

TRAUMATIC GRIEF. Grief resulting from the loss of a loved one in a traumatic situation (natural or transportation disaster, act of terrorism or mass murder, etc.)

TRAUMATIC SHOCK. A condition of depressed body functions as a reaction to injury with loss of body fluids or lack of oxygen. Signs of traumatic shock include weak and rapid pulse; shallow and rapid breathing; and pale, cool, clammy skin.

TRAVELER'S DIARRHEA. An illness due to infection from a bacteria or parasite that occurs in persons traveling to areas where there is a high frequency of the illness. The disease is usually spread by contaminated food or water.

TREMATODE. Any parasitic flatworm of the class Trematoda, as the liver fluke.

TREMOR. Shakiness or trembling.

TREMOR CONTROL THERAPY. A method for controlling tremor by self-administered shocks to the part of the brain that controls intentional movement (thalamus). An electrode attached to an insulated lead wire is implanted in the brain; the battery power source is implanted under the skin of the chest, and an extension wire is tunneled under the skin to connect the battery to the lead. The patient turns on the power source to deliver the electrical impulse and interrupt the tremor.

TRENDELENBURG. Position in which the head is low and the body and legs are on an inclined plane.

TREPHINE. A small surgical instrument that is rotated to cut a circular incision.

TREPONEMA PALLIDUM. The spirochete bacterium that causes syphilis.

TREPONEME. A term used to refer to any member of the genus *Treponema*, which is an anaerobic bacteria consisting of cells, 3–8 μm in length, with acute, regular, or irregular spirals and no obvious protoplasmic structure.

WWW.BOOKBAZ.IR

TRETINOIN. A naturally occurring retinoid, derived from vitamin A, that treats acne by increasing the turnover (death and replacement) of skin cells.

TRIAGE. A system for determining the priority of patients' treatment according to the severity of their injuries in mass casualty situations when it is not possible to treat all patients at once. Triage may be used to prioritize emergency treatment, emergency transport, or the destination of emergency transport.

TRIAL OF LABOR (TOL). A purposeful attempt to deliver vaginally after a previous cesarean delivery.

TRIANGLING. A process in which two family members lower the tension level between them by drawing in a third member.

TRICHIASIS. A disease of the eye, in which the eyelashes, being turned in upon the eyeball, produce constant irritation by the motion of the lids.

TRICHINA. An individual example of *Trichinella spiralis*.

TRICHINOSIS. A roundworm infection, usually contracted by eating raw or undercooked meat. Trichinosis is rare in the United States but a common infection in some parts of the world.

TRICHOMONADS. Parasitic protozoa commonly found in the digestive and genital tracts of humans and other animals. Some species cause vaginal infections in women characterized by itching and a frothy discharge.

TRICHOTILLOMANIA. A disorder marked by repeated pulling and tugging of one's hair, usually resulting in noticeable hair loss on the scalp or elsewhere on the body.

TRICUSPID VALVE. The valve between the right atrium and the right ventricle of the heart.

TRIDOSHA. The combination of three basic principles of energy, or biological humor, that comprise life, according to Ayurvedic philosophy.

TRIGEMINAL NERVES. The fifth and largest pair of cranial nerves; mixed motor-sensory nerves that emerge from the side of the pons in the brainstem.

TRIGEMINAL NEURALGIA. Brief episodes of severe shooting pain on one side of the face caused by inflammation of the root of the trigeminal nerve. Also referred to as tic douloureux.

TRIGGER DRUGS. Specific drugs used for muscle relaxation and anesthesia that can trigger an episode of malignant hyperthermia in a susceptible person. The trigger drugs include halothane, enflurane, isoflurane, sevoflurane, desflurane, methoxyflurane, ether, and succinylcholine.

TRIGLYCERIDE. Chemicals made up mostly of fat that can form deposits in tissues and cause health risks or disease.

TRIIODOTHYRONINE (T_3). A thyroid hormone similar to thyroxine but more powerful. Preparations of triiodothyronine are used in treating hypothyroidism.

TRIMESTER. The first third, or 13 weeks, of pregnancy.

TRIMETHOPRIM-SULFAMETHOXAZOLE (TMP-SMX). An antibiotic used to treat and prevent PCP.

TRINUCLEOTIDE REPEAT EXPANSION. A sequence of three nucleotides that is repeated too many times in a section of a gene.

TRIPLE-NEGATIVE BREAST CANCER. Aggressive and difficult-to-treat breast cancer in which the cells do not express estrogen and progesterone receptors and do not overexpress HER2.

TRIPLOIDY. The condition where an individual has three entire sets of chromosomes instead of the usual two.

TRIPTANS. A class of drugs that bind to serotonin receptors and mimic the action of serotonin; believed to treat migraine headaches by constricting cranial blood vessels, inhibiting inflammatory neuropeptides, and blocking the transmission of pain signals.

TRISOMY. A condition in which a third copy of a chromosome is inherited. Normally only two copies should be inherited.

TRITURATION. The process of diluting a nonsoluble substance for homeopathic use by grinding it to a fine powder and mixing it with lactose powder.

TROCAR. A small sharp instrument used to puncture the abdomen at the beginning of the laparoscopic procedure.

TROPHOBLAST. The tissues that surround an embryo and attach it to the uterus.

TROPHOZOITE. The active feeding stage of a protozoal parasite, as distinct from its encysted stage.

TRUE WEIGHT. Dukan''s term for the weight that a dieter can maintain long term without struggling or damage to health. It takes the dieter's age, sex, family background, pregnancy history, and similar factors

into account. For many people, the true weight may well be higher than what they would consider their ideal weight.

TRYPTOPHAN. An essential amino acid that has to consumed in the diet because it cannot be manufactured by the body. Tryptophan is converted by the body to niacin, one of the B vitamins.

T-SCORE. The score on a bone densitometry test, calculated by comparing the patient's bone mineral density to that of a healthy 30-year-old of the same sex and race.

TUBAL LIGATION. A female sterilization surgical procedure in which the fallopian tubes are tied in two places and cut between. This prevents eggs from moving from the ovary to the uterus.

TUBAL PREGNANCY. Pregnancy in one of the fallopian tubes.

TUBE ENTEROSTOMY. An enterostomy performed to allow the insertion of a feeding tube into the jejunum or stomach.

TUBERCULIN. A mixture of antigens obtained from the cultured bacteria that cause tuberculosis, *Mycobacterium tuberculosis*.

TUBERCULOMA. A tumor-like mass in the brain that sometimes develops as a complication of tuberculosis meningitis.

TUBERCULOSIS. An infectious disease that usually affects the lungs, but may also affect other parts of the body. Symptoms include fever, weight loss, and coughing up blood.

TUBEROUS SCLEROSIS. A rare genetic disease that causes benign tumors to grow in the brain and in other vital organs, including the kidneys, heart, eyes, lungs, and skin. It is thought to be a risk factor for chordoma.

TUBULAR CARCINOMA. A rare genetic disease that causes benign tumors to grow in the brain and in other vital organs, including the kidneys, heart, eyes, lungs, and skin.

TUBULAR KIDNEY DISEASE. Disease of the kidney that affect the tubules, the part of the kidney that allows certain substances to be reabsorbed back into the blood.

TUBULE. A very small tube-shaped structure in the nephron of the kidney that removes certain ions and molecules from the blood and deposits them into the fluid within the tubule.

TUMOR. An abnormal growth of tissue resulting from uncontrolled, progressive multiplication of cells.

TUMOR MARKER. A protein found in blood, urine, or body tissues that can be measured and used to detect the presence of cancer.

TUMOR NECROSIS FACTOR (TNF)-ALPHA. A protein that mediates inflammation and activates immune system cells.

TUMOR-SUPPRESSOR GENE. Gene involved in controlling normal cell growth and preventing cancer.

TUNICA ALBUGINEA. The sheath of elastic tissue enclosing the corpora cavernosa.

TUNICA VAGINALIS. A sac-like membrane covering the outer surface of the testis.

TURBIDIMETRY. A technique of measurement that analyzes the amount of sediment in a liquid.

TURBIDITY. The degree of cloudiness of a urine sample (or other solution).

TURBINADO SUGAR. Sugar made from sugarcane extract that is light brown in color with large crystals; called demerara sugar in the United Kingdom.

TURBINATE. Ridge-shaped cartilage or soft bony tissue inside the nose.

TURNER SYNDROME. A genetic disorder that affects only females, in which one of the two X chromosomes that determine female sex is missing or otherwise abnormal.

TURNING. Turning from side to side permits lung expansion. Patients may turn themselves or be turned by a caregiver. The head of the bed is also elevated to promote drainage if the patient can tolerate this position. Critically ill patients and those dependent on mechanical respiration are turned once every one to two hours around the clock.

25-HYDROXY-VITAMIN D. This is the form of vitamin D that is measured in order to assess vitamin D deficiency.

TWILIGHT ANESTHESIA. An intravenous mixture of sedatives and other medications that decrease a person's awareness of the procedure being performed.

TWIN REVERSED ARTERIAL PERFUSION (TRAP) SEQUENCE. A condition in which one fetus lacks a heart and the other fetus pumps the blood for both.

WWW.BOOKBAZ.IR

TWIN-TO-TWIN TRANSFUSION SYNDROME (TTTS). A condition in monochorionic twins where the connection between the two circulatory systems is such that the donor twin pumps the blood to the recipient twin without the return of blood to the donor.

TYMPANIC MEMBRANE. The eardrum. A thin disc of tissue that separates the outer ear from the middle ear.

TYMPANIC MEMBRANE. The eardrum. A thin disc of tissue that separates the outer ear from the middle ear.

TYMPANOPLASTY. Procedure to reconstruct the tympanic membrane (eardrum) and/or middle ear bone as the result of infection or trauma.

TYMPANOSTOMY TUBE. Ear tube. A small tube made of metal or plastic that is inserted during myringotomy to ventilate the middle ear.

TYPE 1 DIABETES. A chronic immune system disorder in which the pancreas does not produce sufficient amounts of insulin, a hormone that enables cells to use glucose for energy. Also called juvenile diabetes, it must be treated with insulin injections.

TYPE 2 DIABETES. Sometimes called adult-onset diabetes, this disease prevents the body from properly using glucose (sugar) but can often be controlled with diet and exercise.

TYPHOID FEVER. An infectious disease caused by a type of bacterium. People with this disease have a lingering fever and feel depressed and exhausted. Diarrhea and rose-colored spots on the chest and abdomen are other symptoms. The disease is spread through poor sanitation.

TYPICAL USE. A measurement of the effectiveness of a contraceptive that counts all users, including those who use the method incorrectly or only occasionally.

TYRAMINE. A phenolic amine derived from the amino acid tryptophan and found in various foods and beverages, such as cheese and red wine, which can trigger migraines.

TYROSINASE. An enzyme in a pigment cell which helps change tyrosine to DOPA during the process of making melanin.

TYROSINE. A protein building block found in a wide variety of foods that is used by the body to make melanin.

TZANCK PREPARATION. A procedure in which skin cells from a blister are stained and examined under the microscope.

U

UDANA. Life sustaining energy of the diaphragm, the third of the five airs of Ayurvedic philosophy, the life force governing upward motion.

ULCER. A break in the skin or mucous membrane. It can fester and pus like a sore.

ULCERATED. Damaged so that the surface tissue is lost and/or necrotic (dead).

ULCERATION. An open break in surface tissue.

ULCERATIVE COLITIS. Long-lasting and repeated inflammation of the colon with the development of sores.

ULNA. The longer of the two bones in the forearm, extending from the medial side of the elbow joint to the side of the wrist closest to the little finger.

ULNAR COLLATERAL LIGAMENT (UCL) RECONSTRUCTION. The medical name for the Tommy John procedure.

ULNAR NERVE. The nerve that runs close to the ulna and innervates the little finger and ring finger. The longest unprotected nerve in the human body, it is the nerve that aches or tingles when a person hits their "funny bone."

ULTRASONOGRAM. A procedure where high-frequency sound waves that cannot be heard by human ears are bounced off internal organs and tissues. These sound waves produce a pattern of echoes which are then used by the computer to create sonograms, or pictures of areas inside the body.

ULTRASONOGRAPHER. The person who performs the radiologic technique of ultrasound in which deep structures of the body are visualized.

ULTRASONOGRAPHY. A test using sound waves to measure blood flow. Gel is applied to a hand-held transducer that is pressed against the patient's body. Images are displayed on a monitor.

ULTRASOUND. A technique that uses high-frequency sound waves for medical diagnosis and treatment by creating images of internal organs.

ULTRASOUND EXAMINATION. A medical test in which high frequency sound waves are directed at a particular internal area of the body. As the sound waves are reflected by internal structures, a computer uses the data to construct an image of the structures.

ULTRASOUND SCAN. The scan produces images of arteries on a screen and is used to evaluate the blood

flow, locate blockages, and measure the size of the artery.

ULTRASOUND WAVES. High-frequency sound waves.

ULTRAVIOLET (UV) LIGHT. Part of the electromagnetic spectrum with a wavelength just below that of visible light. It is damaging to living material, especially eyes and DNA.

UMBILICAL. Referring to the opening in the abdominal wall where the blood vessels from the placenta enter.

UMBILICAL CORD. The blood vessels that allow the developing baby to receive nutrition and oxygen from its mother; the blood vessels also eliminate the baby's waste products. One end of the umbilical cord is attached to the placenta and the other end is attached to the baby's belly button (umbilicus).

UMBILICUS. The area where the umbilical cord was attached; also known as the navel or belly button.

UNCINATE PROCESS. A downwardly and backwardly directed process of each lateral mass of the ethmoid bone that joins with the inferior nasal conchae.

UNIFOCAL. Only one tumor present in one eye.

UNILATERAL. Located on or affecting only one side of the body.

UNIPARENTAL DISOMY. Chromosome abnormality in which both chromosomes in a pair are inherited from the same parent.

UNRESECTABLE CANCER. A tumor that cannot be completely removed by surgery.

UPPER ENDOSCOPY. A medical procedure in which a thin, lighted, flexible tube (endoscope) is inserted down the patient's throat. Through this tube the doctor can view the lining of the esophagus, stomach, and the upper part of the small intestine.

URATE CRYSTALS. Crystals formed by high levels of uric acid in the blood.

UREA. Chemical formed during the body's metabolism of nitrogen and normally excreted by the kidney. Urea levels rise in the blood when kidney failure occurs.

UREMIA. The presence of excessive amounts of urea and other waste products in the blood.

UREMIC POISONING. Accumulation of waste products in the body.

URETER. The tube that transports urine from the kidney to the bladder.

URETERAL STENT. A surgical device implanted in patients with damaged ureters that holds the ureter open so that urine can flow freely from the kidneys to the bladder.

URETEROVESICAL JUNCTION. The joining of the ureter to the bladder.

URETEROVESICAL VALVE. A sphincter (an opening controlled by a circular muscle), located where the ureter enters the bladder, that keeps urine from flowing backward toward the kidney.

URETHAL. Referring to the tube in humans that carries urine from the bladder out of the body.

URETHRA. The tube that drains urine from the bladder.

URETHRA HYPERMOBILITY. Main factor in stress urinary incontinence, with severity based upon how far the urethra has descended into the pelvic floor through herniation or cystocele.

URETHRAL MEATUS. This is the external opening of the urethra.

URETHRAL STRICTURE. A narrowing of the urethra (urine tube).

URETHRITIS. Inflammation of the urethra, which is the passage through which the urine moves from the bladder to the outside of the body.

URETOSCOPE. A tube-shaped device inserted into the body through the urinary system that allows objects to be both seen and grasped for removal.

URGENCY. A sudden and powerful need to urinate.

URIC ACID. A product of purine breakdown that is excreted by the kidney. High levels of uric acid, caused by various diseases, can cause the formation of kidney stones.

URICOSURIA. Increased levels of uric acid in the urine.

URINALYSIS (PLURAL, URINALYSES). The diagnostic testing of a urine sample.

URINARY CONDUIT DIVERSION. A type of urinary diversion or rerouting that uses a conduit made from an intestinal segment to channel urine to an outside collection pouch.

URINARY INCONTINENCE. Inability to prevent the leakage or discharge of urine. It becomes more

WWW.BOOKBAZ.IR

common as people age, and is more common in women who have given birth to more than one child.

URINARY RETENTION. The inability to void (urinate) or discharge urine.

URINARY TRACT. The passage through which urine flows from the kidneys out of the body.

URINARY TRACT INFECTION (UTI). Common infections often caused by the gut bacterium *Escherichia coli*.

URINE. A fluid containing water and dissolved substances excreted by the kidney.

URINE CREATININE LEVEL. A value obtained by testing a 24-hour collection of urine for the amount of creatinine present.

URINE CULTURE. A test which tests urine samples in the lab to see if bacteria are present.

URINE CYTOLOGY. The examination of the urine under a microscope to look for cancerous or precancerous cells.

URINE DIPSTICK TEST. A test using a small, chemically treated strip that is dipped into a urine sample; when testing for protein, an area on the strip changes color depending on the amount of protein (if any) in the urine.

UROGENITAL. Both the urinary system and the sexual organs, which form together in the developing embryo.

UROGYNECOLOGIST. A physician that specializes in female medical conditions concerning the urinary and reproductive systems.

UROLOGIST. A physician who specializes in treating problems of the urinary tract.

UROLOGY. The branch of medicine that deals with disorders of the urinary tract in both males and females, and with the genital organs in males.

URORADIOLOGIST. A radiologist that specializes in diagnostic imaging of the urinary tract and kidneys.

UROSTOMY. A surgical opening (a stoma) created to divert urine to the outside of the body for collection once the bladder has been removed.

UROTHELIUM. The lining of the urinary tract, including the renal pelvis, ureters, bladder, and urethra.

UTERINE FIBROIDS. Also called leiomyomas; benign growths in the smooth muscle of the uterus.

UTERINE PROLAPSE. A condition in which the uterus descends into or beyond the vagina.

UTERUS. A muscular, hollow organ of the female reproductive tract. The uterus contains and nourishes the embryo and fetus from the time the fertilized egg is implanted until birth.

UVEA. The middle of the three coats of tissue surrounding the eye, comprising the choroid, iris, and ciliary body. The uvea is pigmented and well supplied with blood vessels.

UVEAL TRACT. The pigmented membrane that lines the back of the retina of the eye and extends forward to include the iris. The uveal tract is sometimes called the uvea and has three parts: the iris, the choroid, and the ciliary body.

UVEITIS. Inflammation of the area of the eye around the pupil.

UVULOPALATOPHARYNGOPLASTY (UPPP). An operation to remove excess tissue at the back of the throat to prevent it from closing off the airway during sleep.

V

VACCINATION. Injection of a killed or weakened microbe in order to stimulate the immune system against the microbe, thereby preventing disease. Vaccinations, or immunizations, work by stimulating the immune system, the natural disease-fighting system of the body. The healthy immune system is able to recognize invading bacteria and viruses and produce substances (antibodies) to destroy or disable them. Vaccinations prepare the immune system to ward off a disease. To immunize against viral diseases, the virus used in the vaccine has been weakened or killed.

VACCINE. A preparation containing killed or weakened microorganisms used to build immunity against infection from that microorganism.

VAGINA. The genital canal in the female, leading from the vulva to the uterus.

VAGINAL BIRTH AFTER CESAREAN (VBAC). The option of having subsequent vaginal deliveries after a cesarean delivery.

VAGINAL DISCHARGE. Discharge of secretions from the cervical glands of the vagina; normally clear or white.

VAGINAL PROLAPSE. Bulging of the top of the vagina into the lower vagina or outside the opening of the vagina.

VAGINAL STENOSIS. Narrowing of the vagina due to a buildup of scar tissue.

VAGINAL YEAST INFECTION. An overgrowth of fungus in the vaginal area.

VAGINISMUS. Muscles around the outer third of the vagina have involuntary spasms in response to attempts at vaginal penetration, not allowing for penetration.

VAGINITIS. Inflammation of the vagina.

VAGOTOMY. A surgical procedure in which the nerves that stimulate stomach acid production and gastric motility (movement) are cut.

VAGUS NERVE. The tenth of the 12 pairs of cranial nerves, which receives sensory information from the lungs and the digestive tract, and is also involved in vomiting.

VALACYCLOVIR. An oral antiviral drug that blocks the replication of the varicella zoster virus.

VALIDITY. Measurement validity refers to whether a test is measuring what it claims to.

VALSALVA MANEUVER. Pilots grunt and tighten their abdominal muscles to prevent black outs during high-performance flying.

VALVE. Flaps (leaflets) of tissue in the passageways between the heart's upper and lower chambers.

VALVULAR. Having to do with the valves inside the heart.

VALVULAR HEART DISEASE. A disease of any one of the four valves that controls blood flow into, through, and out of the heart.

VAPING. An informal term for the use of e-cigarettes.

VAPORIZE. To dissolve solid material or convert it into smoke or gas.

VARIABLE DECELERATION. Fetal bradycardia below 100 beats per minute denoting compression of the umbilical cord at the height of a uterine contraction.

VARICELLA. Chickenpox; a disease caused by the *Varicella zoster* virus—human herpes virus 3—that can cause severe birth defects if vertically transmitted during the first 20 weeks of pregnancy and newborn complications if transmitted perinatally.

VARICELLA-ZOSTER IMMUNE GLOBULIN (VZIG). A substance that can reduce the severity of chickenpox symptoms.

VARICES. Swollen or enlarged veins, in this case on the lining of the esophagus.

VARICOCELE. An abnormal enlargement of the veins which drain the testicles.

VARICOSE VEINS. The permanent enlargement and twisting of veins, usually in the legs. They are most often seen in people with occupations requiring long periods of standing, and in pregnant women.

VARIEGATION. Patchy variation in color.

VAS DEFERENS. The duct that stores sperm and carries it from the epididymis to the ejaculatory duct.

VASCULAR. Relating to blood vessels.

VASCULAR SURGERY. A branch of medicine that deals with the surgical repair of disorders of or injuries to the blood vessels.

VASCULITIS. Inflammation of a blood vessel.

VASCULOGENIC ERECTILE DYSFUNCTION. The inability to attain or sustain an erection satisfactory for coitus, due to atherosclerotic disease of penile arteries, inadequate impedance of venous outflow (venous leaks), or a combination of both.

VASECTOMY. Surgical sterilization of the male, done by removing a portion of the tube that carries sperm to the urethra.

VASOCONSTRICTION. Narrowing of blood vessels, especially as a result of vasomotor action.

VASODILATATION. The increase in the internal diameter of a blood vessel that results from relaxation of smooth muscle within the wall of the vessel thus causing an increase in blood flow.

VASODILATOR. A class of drugs that widen the blood vessels, which in turn decreases resistance to blood flow and lowers blood pressure.

VASOPRESSORS. Medications that constrict the blood vessels.

VASOSPASM. Narrowing of a blood vessel caused by a spasm of the smooth muscle of the vessel wall.

VASOVAGAL REACTION. Regarding the action of stimuli from the vagus nerve on blood vessels.

VASOVASOSTOMY. A surgical procedure that is done to reverse a vasectomy by reconnecting the ends of the severed vasa deferentia.

WWW.BOOKBAZ.IR

VATA. One of the three main constitutional types found under Ayurvedic principles. Keeping one's particular constitution in balance is considered important in maintaining health.

VECTOR. An organism, such as insects or rodents, that can transmit disease to humans.

VEGAN. A strict vegetarian diet, which does not include eggs, meat, dairy products, and all other dietary choices derived from animals.

VEGETATION. An abnormal growth of tissue around a valve, composed of blood platelets, bacteria, and a protein involved in clotting.

VEIN. A blood vessel that returns oxygen-depleted blood from various parts of the body to the heart.

VENA CAVA. The large vein that drains directly into the heart after gathering incoming blood from the entire body.

VENIPUNCTURE. The withdrawal of blood from a patient's vein for purposes of testing or research. The most common procedure used in adults involves the withdrawal of blood from the medial cubital vein near the elbow using a hypodermic needle and a vacuum tube.

VENOARTERIAL (V-A) BYPASS. The type of ECMO that provides both heart and lung support, using two tubes (one in the jugular vein and one in the carotid artery).

VENOM. A poisonous substance secreted by an animal, usually delivered through a bite or a sting.

VENOUS STASIS DISEASE. A condition in which there is pooling of blood in the lower leg veins that may cause swelling and tissue damage, and lead to painful sores or ulcers.

VENOUS VALVES. Folds on the inner lining of the veins that prevent the backflow of blood.

VENOVENOUS (V-V) BYPASS. The type of ECMO that provides lung support only, using a tube inserted into the jugular vein.

VENTILATOR. A mechanical device that can take over the work of breathing for a patient whose lungs are injured or are starting to heal.

VENTRICLE. Either one of two lower chambers (left and right) of the heart that receives blood from the upper chambers (atria) and then pumps that blood into the arteries.

VENTRICULAR DRAIN. Used to measure the pressure inside the head or to relieve a blockage of the flow of the CSF.

VENTRICULAR FIBRILLATION. An erratic, disorganized firing of impulses from the ventricles, the lower chambers of the heart. The ventricles quiver instead of pumping in an organized way, preventing blood from pumping through the body. Ventricular fibrillation is a medical emergency that must be treated with cardiopulmonary resuscitation (CPR) and defibrillation as soon as possible.

VENTRICULAR SEPTAL DEFECT (VSD). A defect or opening in the ventricular septum, the wall of tissue that separates the two lower chambers of the heart.

VENTRICULAR SHUNT. A tube that is placed in one of the fluid filled chambers inside the brain (ventricles) to drain excess fluid and relieve pressure.

VENTRICULAR TACHYCARDIA. An abnormally rapid heartbeat. It includes a series of at least three beats arising from a ventricular area at a rate of more than 100 beats per minute, usually ranging from 150–200 beats per minute.

VENTRICULOSTOMY. Surgery that drains cerebrospinal fluid from the brain to treat hydrocephalus or increased intracranial pressure.

VERMILION BORDER. The line between the lip and the skin.

VERTEBRAE. Bones in the cervical, thoracic, and lumbar regions of the body that make up the vertebral column. Vertebrae have a central foramen (hole), and their superposition makes up the vertebral canal that encloses the spinal cord.

VERTEBRAL COLUMN. The vertebral column, also called the spinal column or spine, consists of a series of vertebrae connected by ligaments. It provides a supporting axis for the body and protects the spinal cord. The vertebral column consists of seven cervical vertebrae in the neck, followed by 12 thoracic vertebrae that connect to the ribs, five lumbar vertebrae in the lower back, the sacrum, and the coccyx.

VERTEBROBASILAR ARTERIES. Major blood vessels that lead to the brain. They are located at the base of the skull at the back of the head.

VERTIGO. A sensation of dizziness marked by the feeling that one's self or surroundings are spinning or whirling.

VESICLE. A bump on the skin filled with fluid.

VESTIBULAR. Pertaining to the vestibule; regarding the vestibular nerve of the ear which is linked to the ability to hear sounds.

VESTIBULAR SYSTEM. The area of the inner ear that helps maintain balance.

VESTIBULE. Vestibule of the vulva or vagina; the space between the labia minora containing the openings of the vagina and urethra.

VESTIBULECTOMY. Surgical removal of the vestibule and hymen.

VESTIBULOCOCHLEAR NERVE (EIGHTH CRANIAL NERVE). Nerve that transmits information, about hearing and balance from the ear to the brain.

VIAGRA. Trade name of an orally administered drug for erectile failure first cleared for marketing in the United States in March 1998. Its generic name is sildenafil citrate.

VIBRATION. The purpose of vibration is to help break up lung secretions. Vibration can be either mechanical or manual. It is performed as the patient breathes deeply. When done manually, the person performing the vibration places his or her hands against the patient's chest and creates vibrations by quickly contracting and relaxing arm and shoulder muscles while the patient exhales. The procedure is repeated several times each day for about five exhalations.

VIBROACOUSTIC STIMULATION. In the biophysical profile, use of an artificial larynx to produce a loud noise to "awaken" the fetus.

VIDEO-ASSISTED THORACIC SURGERY (VATS). A technique used to aid in the placement of chest tubes or when performing decortications when treating advanced empyema.

VIDEOSCOPE. A flexible surgical camera that produces video images comparable to that of a high-end camcorder.

VILLI. Tiny, finger-like projections that enable the small intestine to absorb nutrients from food.

VIRAL LOAD. The number of copies of a virus in one milliliter of blood; used to measure the severity of HIV and other viral infections.

VIRAL LOAD TEST. A new blood test for monitoring the speed of HIV replication in AIDS patients. The viral load test is based on PCR techniques and supplements the CD4+ cell count tests.

VIREMIC. The presence of viruses in the blood.

VIRTUAL COLONOSCOPY. A noninvasive form of colonoscopy that uses computed tomography (CT scanning) to obtain images of the interior of the patient's colon and rectum. It is also called CT colonography.

VIRULENCE. The degree of a disease organism's ability to produce illness, as indicated by the mortality rate and/or the organism's ability to invade the host's tissues.

VIRUS. A tiny, disease-causing structure that can reproduce only in living cells and causes a variety of infectious diseases.

VISCERA. Any of the body's organs located in the chest or abdomen.

VISCERAL LARVA MIGRANS (VLM). Another name for toxocariasis. The name is derived from the life cycle of the organism.

VISUAL ACUITY. The ability to distinguish details and shapes of objects.

VISUAL ACUITY TEST. An eye examination that determines sharpness of vision, typically performed by identifying objects and/or letters on an eye chart.

VISUALIZATION. The process of making an internal organ visible. A radiopaque substance is introduced into the body, then an x-ray picture of the desired organ is taken.

VISUAL-MOTOR. The ability to coordinate vision and bodily movements.

VISUAL-MOTOR SKILLS. Hand-eye coordination; in the Bender-Gestalt test, visual-motor skills are measured by the subject's ability to accurately perceive and then reproduce figures.

VISUAL-PERCEPTUAL SKILLS. The capacity of the mind and the eye to "see" something as it objectively exists.

VISUAL-SPATIAL. The ability to manipulate multidimensional figures mentally.

VITAL CAPACITY (VC). Maximal breathing capacity; the amount of air that can be expired after a maximum inspiration.

VITAL SIGNS. Basic indicators of body function, usually meaning heartbeats per minute, breaths per minute, blood pressure, body temperature, and weight.

VITAMIN. A nutrient that the body needs in small amounts to remain healthy but that the body cannot manufacture for itself and must acquire through diet.

WWW.BOOKBAZ.IR

VITAMIN B12. A water-soluble, cobalt-containing member of the complex of eight B vitamins that is required for many bodily functions, sometimes in conjunction with vitamin B_6 and folic acid.

VITAMIN D. Any of several fat-soluble vitamins that are required for normal bone and teeth structure and various other physiological functions. Vitamin D is obtained from some foods and is produced in the body through the action of ultraviolet radiation.

VITAMIN K. A vitamin that is required for producing prothrombin in the liver.

VITILIGO. A chronic skin disorder that causes loss of pigmentation (color) from patches of skin, most often on the face, hands, and wrists.

VITREOUS. The transparent gel that fills the back part of the eye.

VITREOUS SEEDING. When small pieces of tumor have broken off and are floating around the vitreous.

VOCATIONAL. Relating to an occupation, career, or job.

VOICE BOX. The larynx.

VOIDING. The medical term for emptying the bladder or urinating.

VOLATILE. Something that vaporizes or evaporates quickly when exposed to air.

VOLATILE ORGANIC COMPOUNDS. VOCs, a large class of carbon-based chemicals that release gases into the air as they evaporate at room temperature. Found both in natural sources such as living trees, decomposing vegetation, and crude oil, and in manmade sources such as solvents, adhesives, and gasoline, VOCs help form ozone at ground levels and are major air contaminants.

VOLATILE SOLVENTS. Liquids that vaporize at room temperature, including a variety of industrial and household products and art and office-supply solvents.

VOLTAGE. The force necessary to drive an electric current between two specified points. A large voltage exerts a greater force, which moves more electrons through a wire at a given rate of time.

VOLUNTARY. An action or thought undertaken or controlled by a person's free will or choice.

VOLUNTARY MUSCLE. A muscle under conscious control, such as arm and leg muscles.

VOLVULUS. A twisted loop of bowel, causing obstruction.

VON WILLEBRAND FACTOR (VWF). A protein found in the blood that is involved in the process of blood clotting.

VON WILLEBRAND'S DISEASE. An inherited lifelong bleeding disorder caused by an abnormal gene, similar to hemophilia. The gene defect results in a decreased blood concentration of a substance called von Willebrand's factor (vWF).

VOYEURISM. Sexual stimulation by visual means, usually by observing an unsuspecting individual.

VULVA. The external female genital organs, including the labia majora, labia minora, clitoris, and vestibule of the vagina.

VULVAR VESTIBULITIS. A localized inflammation of the vestibule—the region immediately surrounding the opening of the vagina and the urethra.

VULVODYNIA. A chronic burning, stinging, or irritation of the vulva.

VYANA. Life sustaining energy of the heart and lungs; the second of the five airs of Ayurvedic philosophy; the life force governing circular motion.

W

WARFARIN. A blood thinner or anticoagulant use to prevent blood clots; its activity is monitored by PT tests.

WART. A raised growth on the surface of the skin or other organ.

WARTHIN'S TUMOR. A benign tumor of the parotid gland.

WASTING. Weight more than two standard deviations below that of the median weight for the reference population.

WASTING SYNDROME. Weight loss and changes in the composition of body tissues—typically the replacement of lean muscle tissue with fat—that occur in HIV/AIDS patients.

WATER BRASH. The flow of saliva and stomach acid back up the esophagus and into the throat or lungs.

WATER INTOXICATION. A potentially life-threatening condition caused by drinking too much water, which leads to hyponatremia and may result in seizures, coma, and death.

WATER-SOLUBLE VITAMIN. A vitamin that dissolves in water and can be removed from the body in urine.

WBC DIFFERENTIAL. A white blood cell count in which the technician classifies the different white blood cells by type as well as calculating the number of each type. A WBC differential is necessary to calculate the absolute CD4+ lymphocyte count.

WEGENER'S GRANULOMATOSIS. A disease usually affecting males that causes the infiltration of inflammatory cells and tissue death in the lungs, kidneys, blood vessels, heart, and other tissues.

WEIGHT CYCLING. Repeatedly gaining and losing weight.

WERNICKE'S APHASIA. A condition characterized by either partial or total loss of the ability to understand what is being said or read. The individual maintains the ability to speak, but speech may contain unnecessary or made-up words.

WERNICKE-KORSAKOFF SYNDROME. A combination of symptoms, including eye-movement problems, tremors, and confusion, that is caused by a lack of the B vitamin thiamine and may be seen in alcoholics.

WEST NILE VIRUS. A virus related to ZIKV and causing an illness similar to zika fever, but which sometimes develops into encephalitis or meningitis.

WESTERN BLOT. A procedure for detecting the presence of specific antibodies in a sample; used to confirm the results of an HIV screening test.

WHEEZE. A whistling sound made by the flow of high-velocity air through narrowed airways. Wheezing is a symptom of several respiratory diseases including byssinosis and asthma.

WHIPPLE PROCEDURE. Surgical removal of the head of the pancreas, part of the small intestine, and some surrounding tissue.

WHIPPLE'S DISEASE. A disorder of impaired absorption of nutrients by the small intestine. Symptoms include diarrhea, abdominal pain, progressive weight loss, joint pain, swollen lymph nodes, abnormal skin pigmentation, anemia, and fever. The precise cause is unknown but it is probably due to an unidentified bacterial infection.

WHIPWORM. A nematode worm of the family Trichuridae with a body that is thick at one end and very long and slender at the other end.

WHITE BLOOD CELLS (LEUKOCYTES). A class of cells in the blood that form the foundation of the body's immune system.

WHOLE BLOOD. Blood that contains red blood cells, white blood cells, and platelets in plasma.

WHOOPING COUGH. An infectious disease of the respiratory tract caused by a bacterium, *Bordetella pertussis*.

WILDCRAFTING. Gathering of herbs or other natural materials.

WILDERNESS. Large backcountry areas lacking roads, communication, and other modern infrastructure.

WILSON'S DISEASE. A genetic disorder in which copper accumulates in the body, leading to liver disease and a variety of neurological and psychiatric symptoms.

WINDOW. A perspective adopted to assess the property of a given plant.

WINDOW. The term used in intermittent fasting to refer to the time period when eating is allowed. It is also called the eating window.

WINDOW OPERATION. Cutting out a large oval-shaped piece of the cyst wall and putting in stitches to create a window so the cyst cannot reoccur.

WIRELESS CAPSULE ENDOSCOPY. A newer method of examining the small bowel by means of a capsule swallowed by the patient. The capsule contains a miniaturized lens and an antenna that transmits information to a belt-pack recorder worn by the patient during the day.

WISDOM TOOTH. One of the four last teeth on the top and bottom rows of teeth. Also called a third molar.

WISKOTT-ALDRICH SYNDROME (WAS). A rare X-linked recessive disease that involves an abnormal immune system and reduced ability to form blood clots; it is associated with such medical conditions as bloody diarrhea, eczema, immune deficiency, and thrombocytopenia.

WITHDRAWAL. The unpleasant, sometimes life-threatening, physiological changes that can occur due to the discontinuation of alcohol or drugs after prolonged regular use.

WITHDRAWAL SYMPTOMS. A group of physical or mental symptoms that may occur when a person suddenly stops using a drug to which he or she has become dependent.

WOLFF-PARKINSON-WHITE SYNDROME. An abnormal rapid heart rhythm, due to an extra pathway for the electrical impulses to travel from the atria to the ventricles.

WWW.BOOKBAZ.IR

WOMEN'S HEALTH INITIATIVE (WHI). A very large clinical study supported by the National Heart, Lung, and Blood Institute and the National Cancer Institute of the U.S. National Institutes of Health that is examining a wide range of women's health issues including HRT.

WOOD'S LAMP. A special lamp that uses ultraviolet light to detect certain types of skin infections and infestations. It was invented in 1903 by a physicist named Robert Wood.

WORD CATHETER. A small rubber catheter with an inflatable balloon tip that is inserted into a stab incision in the cyst, after the contents of the cyst have been drained.

WORD SALAD. Speech that is so disorganized that it makes no linguistic or grammatical sense.

WRIGHT'S STAIN. A chemical used to stain tissue samples for laboratory analysis.

X

X CHROMOSOME. One of the two types of sex chromosomes; females have two X chromosomes, while males have one X chromosome and one Y chromosome.

X RAY. A form of electromagnetic radiation with shorter wavelengths than normal light. X rays can penetrate most structures.

XANTHOMAS. Fatty yellow patches or nodules on the skin or internal tissues.

XENOGRAFT. Tissue that is transplanted from one species to another (e.g., pigs to humans).

XENOTRANSPLANT. Transplantation of animal cells or tissues into a human.

XERODERMA PIGMENTOSUM. A genetic disease characterized by the inability to repair damaged DNA. Individuals with this disease develop an excessive number of skin cancers.

XEROPHTHALMIA. A drying of the cornea and conjunctiva.

XEROSTOMIA. The medical term for dry mouth.

X-LINKED. Located on the X chromosome, one of the sex chromosome-linked genes follow a characteristic pattern of inheritance from one generation to the next.

X-LINKED DOMINANT INHERITANCE. The inheritance of a trait by the presence of a single gene on the X chromosome in a male or female, passed from an affected female who has the gene on one of her X chromosomes.

X-LINKED HYPOPHOSPHATEMIA. A type of rickets caused by genetic factors which prevent the kidneys from retaining phosphate.

X-LINKED RECESSIVE INHERITANCE. The inheritance of a trait by the presence of a single gene on the X chromosome in a male, passed from a female who has the gene on one of her X chromosomes, and who is referred to as an unaffected carrier.

Y

YELLOW FEVER. An infectious disease caused by a virus. The disease, which is spread by mosquitoes, is most common in Central and South America and Central Africa. Symptoms include high fever, jaundice (yellow eyes and skin) and dark-colored vomit, a sign of internal bleeding. Yellow fever can be fatal.

YIN/YANG. Universal characteristics used to describe aspects of the natural world.

YOGA. A system of physical, mental, and breathing exercises developed in India.

YOGI (FEMALE, YOGINI). A trained practitioner of yoga.

YOLK SAC. A sac made of membranous tissue that is attached to the embryo and provides nutrition to the embryo.

YUPZE REGIMEN. A form of emergency contraception in which two oral contraceptive pills that contain both of the hormones estrogen and progestin are taken to prevent pregnancy.

Z

ZAFIRLUKAST (ACCOLATE). An inhibitor that prevents leukotrienes from binding to cell receptors; taken over time, zafirlukast can help reduce or prevent asthma symptoms.

ZELLWEGER SPECTRUM. Three peroxisome biogenesis disorders—Zellwinger syndrome, neonatal adrenoleukodystrophy, and infantile Refsum disease—which can be caused by different mutations in the same genes and which differ only in the severity of the resulting condition.

ZEN. A form of meditation that emphasizes direct experience.

ZIKV. The virus that causes zika fever.

ZILEUTON (ZYFLO). A medication that interferes with the biosynthetic pathway that produces leukotrienes; used to help prevent asthma attacks.

ZOLLINGER-ELLISON SYNDROME. A rare condition characterized by severe and recurrent peptic ulcers in the stomach, duodenum, and upper small intestine, caused by a tumor, or tumors, usually found in the pancreas. The tumor secretes the hormone gastrin, which stimulates the stomach and duodenum to produce large quantities of acid, leading to ulceration. Most often cancerous, the tumor must be removed surgically; otherwise total surgical removal of the stomach is necessary.

ZONE THERAPY. Also called zone analgesia, a method of relieving pain by applying pressure to specific points on the body. It was developed in the early twentieth century by Dr. William Fitzgerald.

ZOONOSIS (PLURAL, ZOONOSES). Any disease of animals that can be transmitted to humans under natural conditions. Lyme disease, rabies, psittacosis (parrot fever), cat-scratch fever, and monkeypox are examples of zoonoses.

ZOONOTIC. Diseases that can be transmitted from animals to humans under natural conditions.

ZYGOMYCOSIS. Another term for mucormycosis. The fungi that cause mucormycosis belong to a group called Zygomycetes.

ZYGOTE. The result of the sperm successfully fertilizing the ovum. The zygote is a single cell that contains the genetic material of both the mother and the father.

INDEX

The index is alphabetized using a word-by-word system. References to individual volumes are listed before colons; numbers following a colon refer to specific page numbers within that particular volume. **Boldface** references indicate main topical essays. Photographs and illustration references are highlighted with an italicized page number. Tables and figures are indicated with the page number followed by a lowercase, italicized *t*.
